ABSTRACT

Alzheimer’s disease is a chronic, progressive, neurodegenerative brain disorder that occurs gradually and characterized by disturbance of multiple cortical functions including memory, judgment, orientation, comprehension, learning capacity and language. The present study was undertaken to evaluate the nootropic potential of leaves of Trigonella foenum-graceum Linn. Various concentrations of Trigonella foenum leaf powder (TFLP) was administered along with the specially prepared diet for 15 successive days to different groups of young and aged mice. The learning and memory scores were assessed by using both interoceptive and exteroceptive model of amnesia. Trigonella foenum leaf powder produced a significant dose dependent improvement in memory of young and aged mice. The feeding of TFLP for 15 successive days showed a marked decrease in brain acetyl cholinesterase, malondialdehyde and increase in reduced glutathione level. Apart from this, it also decreases the serum cholesterol and glucose levels in mice. Moreover, it also reversed the amnesia produced by scopolamine, diazepam and natural aging process. Thus, the nootropic potential of Trigonella foenum may be attributed to (i) lowered serum cholesterol and glucose levels (ii) increased cholinergic transmission in mouse brain (iii) decreased lipid per-oxidation and elevated the reduced glutathione level in mouse brain and therefore ultimately improved memory of both young and aged mice. It can be of enormous use in the management of mental disorders like Alzheimer’s disease.

Keywords: Trigonella foenum, Alzheimer’s disease, Elevated plus maze, Nootropic, Anticholinergic, Hypolipidemic.

INTRODUCTION

Stressful lifestyle in this competitive world may be the root cause of mental illness such as Alzheimer and other memory related disorders. Dementia associated with Alzheimer has gripped human population world over and it has become an important area of research interest. Alzheimer’s disease is an irreversible, chronic, progressive neurodegenerative brain disorder characterized by the development of senile plaques and neurofibrillary tangles, which are associated with neuronal loss affecting cholinergic neurons to a greater extent and results in memory loss, unusual behavior, personality changes and ultimately death.

Nootropics are a class of psychotropic drugs with selective facilitatory effect on integrative functions of the central nervous system, mainly on intellectual performance, learning capability and memory. Nootropic agents such as piracetam, lamotrigine, aniracetam and choline esterase inhibitors like Donepezil are presently used for improving memory, mood and behavior. However, due to increase incidence of side effects of allopathic medicine (both nootropic and cholinesterase inhibitors) more research will be manifested toward the use of natural resources for the management of various cognitive disorders.

Trigonella foenum-graceum (L) is commonly known as fenugreek, alholva, menthi, trigonilla and methi in India. The plant has traditionally been used as carminative, demulcent, expirant, laxative, and stomachic. It has also been used topically for abscesses, boils, burns, eczema, gout and ulceration of the skin. Moreover, further research envisaged that the plant also possess immunomodulatory, anti-fertility, anti-hyperglycemic, anti-pyretic, anti-inflammatory, galactogogue, antioxidant, anticancer, antiplatelet, antihypertensive, cardio- tonic, antibacterial, antihistamaniac, analgesic, anti-ulcer activity. Therefore, the aim of present work was to investigate the nootropic potential of Trigonella foenum leaf powder in mice.

MATERIALS AND METHODS

Plant material

The dried leaves of Trigonella foenum were purchased in the month of July from local market of Hisar, Haryana, India. The plant material was shade dried and ground into a fine paste using an electric grinder. Different concentrations of TFLP (5, 10, 15 % w/w) were fed to separate groups of mice through a specially prepared diet. This special diet comprised of a mixture of TFLP, wheat flour kneaded with water, a small amount of refined vegetable oil and a pinch of salt (sodium chloride), to impart taste. Each animal consumed around 3 gm/day of this specially prepared diet. Control animals received the normal diet consisting of wheat flour, kneaded with water, small amount of refined vegetable oil and a pinch of salt but without TFLP.

Acute Toxicity Studies

TFLP was administered orally at different doses (5-25 % w/w) to mice with a specially prepared diet. TFLP was administered at the
same time on each day (8 AM - 9 AM). During the first four hours after the drug administration, the animals were observed for gross behavioral changes if any, for 7 days. Parameters such as hyperactivity, grooming, convulsions, sedation, hyperthermia and mortality were observed. The doses selected were 5, 10 and 15 % w/w/day.

**Exteroceptive Behavioural Models**

**Elevated Plus Maze**

Elevated plus maze served as the exteroceptive behavioral model to evaluate learning and memory in mice. The elevated plus maze for mice consisted of two open arms (16 cm × 5 cm) and two covered arms (16 cm × 5 cm × 12 cm) extended from a central platform (5 cm × 5 cm) and the maze was elevated to a height of 25 cm from the floor. On the first day, each mouse was placed at the end of an open arm, facing away from the central platform. Transfer latency (TL) was recorded on the first day (training) for each animal. The mouse was allowed to explore the maze for another 2 minutes and then returned to its home cage. Retention of this learned-task (memory) was examined 24 h after the first day trial.

**Passive Avoidance Paradigm**

Passive Avoidance Behavior based on negative reinforcemen was used to examine the long-term memory. The apparatus consisted of a box (27 cm × 27 cm × 27 cm) having three walls of wood and one wall of plexiglass, featuring a grid floor (made up of 3 mm stainless steel rods set 8 mm apart), with a wooden platform (10 cm × 7 cm × 1.7 cm) in the center of the grid floor. The box was illuminated with a 15 W bulb during the experimental period. Electric shock (20 V, A.C.) was delivered to the grid floor. Training was carried out in two similar sessions. Each mouse was gently placed on the wooden platform set in the center of the grid floor. When the mouse stepped down placing all its paws on the grid floor, shocks were delivered for 15 seconds and the step-down-latency (SDL) was recorded. Animals showing SDL in the range of 2-15 seconds during the first test were used for the second session and the retention test. The second session was carried out 90 minutes after the first test. During second session, if the animals stepped down before 60 seconds, electric shocks were delivered once again for 15 seconds. During the second test, animals were removed from shock free zone, if they did not step down for a period of 60 seconds and were subjected to retention test. Retention was tested after 24 h in a similar manner, except that the electric shocks were not applied to the grid floor observing an upper cut-off time of 300 seconds.

**Biochemical Estimations**

**Collection of Blood and Brain samples**

The animals were sacrificed by cervical decapitation under light anesthesia on the 15th day, 90 minutes after diet. Immediately after decapitation, the trunk blood was collected. Then whole brain was carefully removed from the skull. The collected blood was centrifuged at 3000 rpm for 15 minutes so as to separate the serum. The serum was used for estimation of total cholesterol and glucose levels. For preparation of brain homogenate, fresh whole brain was weighed and transferred to a glass homogenizer and homogenized in an ice bath after adding 10 volumes of 0.9 % sodium chloride solution. The homogenate was centrifuged at 3000 rpm for 10 minutes and the resultant cloudy supernatant liquid was used for estimation of brain acetyl cholinesterase (AChE) activity, malonaldehyde (MDA) and reduced glutathione (GSH) level.

**Estimation of Brain Cholinesterase**

Brain cholinesterase activity was measured by the method of colorimetric measurement. The 0.5 ml of the cloudy supernatant liquid was pipetted into 25 ml volumetric flask and dilution was made with a freshly prepared DTNB (5,5-dithio-2-nitrobenzoic acid solution (10 mg DTNB in 100 ml of sorenson phosphate buffer, pH 8.0). From the volumetric flask, two 4 ml portions were pipetted out into two test tubes. Into one of the test tubes, 2 drops of eserine solution was added. 1ml of substrate solution (75 mg of acetylcholine iodide per 50 ml of distilled water) was pipetted out into both the tubes and incubated for 10 minutes at 30˚C. The solution in the tube containing eserine was used for zeroing the colorimeter. The resulting yellow color was due to reduction of DTNB by certain substances in the brain homogenate and due to non-enzymatic hydrolysis of substrate. After calibrating the instrument, change in absorbance per min of the sample was read at 420 nm.

**Estimation of Brain Malonaldehyde (MDA)**

Malonaldehyde, indicator of lipid peroxidation was determined as described by Ohkawa et al, with slight modification. The reaction mixture consisted of 0.2 ml of 8.1 % sodium laurel sulphate, 1.5 ml of 20 % acetic acid (pH 3.5) and 1.5 ml of 0.8 % aqueous solution of thio-barbituric acid was added to the 0.2 ml of processed brain homogenate. The mixture was made up to 4.0 ml with distilled water and heated at 95˚C for 60 minutes. After cooling with tap water, 5 ml of n-butanol and pyridine (15:1 v/v) and 1 ml of distilled water was added and centrifuged. The organic layer was separated out and its absorbance was measured at 532 nm using a UV-Visible spectrophotometer and MDA content was expressed as nmole/mg of protein. Tissue protein was estimated using Lowry method of protein assay.

**Estimation of Brain Reduced Glutathione (GSH)**

GSH estimation in brain homogenate was measured according to the Ellman method. This method is based on the development of a yellow color when 5,5'-dithio-2-nitrobenzoic acid is added to the compound containing the sulphydryl groups. To the 0.5 ml of brain homogenate was mixed with 1.5 ml of 0.2 M Tris buffer (pH-8.2) and 0.1 ml of 0.01M DTNB and this mixture was brought to 10.0 ml with 7.9 ml of absolute methanol. The above reaction mixture is centrifuged at approximately 300 g at room temperature for 15 minutes. The absorbance of supernatant was read in a spectrophotometer against reagent blank (without sample) at 412 nm. Tissue protein was estimated using Lowry method of protein assay.

**Estimation of Serum Total Cholesterol Level**

CHOD-PAP method was used for the estimation of serum total cholesterol. In this method, the blank sample, standard sample and test sample were pipetted into the respective reaction vessels using a micro pipette. For the blank sample, 20 μl of distilled water and 1000 μl of working reagent were mixed. For the standard sample, 20 μl of standard cholesterol and 1000 μl of working reagent, while for the test sample, 20 μl of serum and 1000 μl of working reagent were mixed. These mixtures were incubated for 10 minutes at 37˚C. The absorbance was read at 510 nm and 630 nm (Filter 1 and Filter 2) against the blank sample by using autoanalyzer (Erba Mannheim Chem-5 plus V.)

**Estimation of Blood Glucose Level**

GOD-POD method was used for the estimation of blood glucose using Auto analyzer. In this method, the blank sample, standard sample and test sample was pipetted into the respective reaction vessels using a micropipette. For the blank sample, 10 μl of distilled water and 1000 μl of working reagent were mixed. For the standard sample, 10 μl of standard glucose and 1000 μl of working reagent, while for the test sample, 10 μl of serum and 1000 μl of working reagent were mixed. These mixtures were incubated for 15 minutes at 37˚C. The absorbance was read at 510 nm and 630 nm (Filter 1 and Filter 2) against the blank sample by using Auto-analyzer (Erba Mannheim Chem-5 plus V.)

**Statistical Analysis**

All the results were expressed as Mean ± Standard Error (SEM). Data was analyzed using one-way ANOVA followed by Dunnett’s t-test. Values of P < 0.05 were considered as significant change.
Acute Toxicity Study

No mortality was observed following oral administration of TFLP even with the highest dose 25 % w/w. However at doses more than 20 % w/w produced profuse Black watery stools in animals. The above selected doses of TFLP had no toxic effect on the normal behavior of the rats.

RESULTS

Acute Toxicity Study

No mortality was observed following oral administration of TFLP even with the highest dose 25 % w/w. However at doses more than 20 % w/w produced profuse Black watery stools in animals. The above selected doses of TFLP had no toxic effect on the normal behavior of the rats.

Effect on TL (Using Elevated plus maze)

Mice readily accepted the specially prepared diet containing TFLP, when compared to their normal diet. Transfer latency on second day reflected retention of learned task or memory. The young mice fed with specially prepared diet containing 5, 10 and 15 % w/w of TFLP showed a dose dependent (p<0.01) reduction in TL of 15th day indicating significant improvement of memory, when compared with control groups (Fig. 1). These concentrations of TFLP 5, 10 and 15 % w/w of diet also produced significant memory improvement (p<0.01) in aged mice (Fig. 2). The acute single dose pretreatment of scopolamine (0.4 mg/kg, i.p.) and diazepam (1 mg/kg, i.p.) before training significantly increased (p<0.01) the TL on 15th day indicating impairment of memory. The mice treated chronically for 15 successive days with TFLP (5, 10 and 15 % w/w, respectively) mixed in specially prepared diet was fed to aged mice for 15 successive days. The animals were sacrificed 90 minutes after the specially prepared diet of day 15th and retention was recorded for estimation of brain cholinesterase, blood glucose and total cholesterol levels.

Effect on SDL (Using Passive Avoidance Paradigm)

Step down latency (15th day of drug treatment) reflected long term memory of animals. The young mice fed with diet containing 5, 10 and 15 % w/w of TFLP for 15 days, showed a dose dependent (p<0.01) increase in SDL of 15th day when compared with control group (Fig. 5). The acute single dose pretreatment of scopolamine (0.4 mg/kg i.p.) and diazepam (1 mg/kg i.p.) before training significantly decreased (p<0.01) the SDL of 15th day indicating impairment of memory. The mice treated chronically for 15 successive days with TFLP (5, 10 and 15 % w/w of diet) countered successfully scopolamine (Fig. 6) as well as diazepam induced amnesia (Fig. 6). Piracetam (used as positive control) at the dose of 400 mg/kg i.p. also improved memory (p<0.01) of both young and aged mice and reversed the amnesia induced by scopolamine and diazepam as expected.

Values are in mean ± SEM (n=6): * denotes p <0.05 as compared to control group of young mice. ** denotes p < 0.01 as compared to control group of young mice. ●● denotes p < 0.01 as compared to Diazepam group of young mice. ♦♦ denotes p < 0.01 as compared to Scopolamine group of young mice. (One-way ANOVA followed by Dunnett’s t-test).
Effect on Brain Acetyl Cholinesterase Activity

TFLP (5, 10 and 15 % w/w of diet for 15 days) showed profound reduction in brain cholinesterase level in young and aged mice, as compared to respective control groups by using Ellman’s kinetic colorimetric method (Fig. 7). The percentage reductions in cholinesterase activity in young mice were 22.38 % (p<0.01), 26.68 % (p<0.01) and 30.26 % (p<0.01) at various concentrations of TFLP (5, 10 and 15 % w/w) of diet. Donepezil (0.1 mg/kg i.p.), a standard AChE inhibitor produced 33.7 % and 45.6 % inhibition of AChE enzyme activity in young and aged mice respectively where as the percentage inhibition of reductions of cholinesterase activity were 25.10 %, 30.8 % (p<0.01) and 34.97 % (p<0.01) at respective concentrations of TFLP 5, 10 and 15 % w/w of diet in aged mice.

Effect on Total Cholesterol Level

The animals receiving TFLP (5, 10 and 15 % w/w of diet p.o.) for 15 days consecutively showed significant reduction in total cholesterol levels in young and as well as aged mice (Fig. 8). The extent of reduction of cholesterol in young mice were found to be 5.20 %, 22.75 % (p<0.001) and 33.40 % (p<0.001) at doses of TFLP 5, 10 and 15 % of diet respectively. Simvastatin, a standard cholesterol lowering agent evoked reduction in cholesterol levels 45.78 % (p<0.001) and 36.76 % (p<0.001) in young and aged mice respectively. The extent of reduction in total serum cholesterol levels of aged mice were 9.68 %, 22.95 % (p<0.001) and 28.75 % (p<0.001) at doses of TFLP (5, 10 & 15 %) of diet respectively.

Fig. 7: Effect of TFLP (5, 10 and 15 % w/w) on brain acetyl cholinesterase activity of young and aged mice

Values are expressed as Mean ± SEM, (n=6). * & ■ denotes p < 0.05 when compared to control group of Young & aged mice. ** & ■ ■ denotes p < 0.01 when compared to control group of Young & aged mice. (One-way ANOVA followed by Dunnett’s t-test).

Effect on Serum Glucose Level

The animals receiving TFLP (5, 10 and 15 % w/w of diet) for 15 days consecutively showed significant (p<0.01) reduction in blood glucose levels of young and aged mice, when compared to the respective control groups (Fig. 9). The extent of reduction in serum glucose levels of young mice were 12.29 %, 19.45 % (p<0.01) and 30.31 % (p<0.01) at the concentrations of 5, 10 and 15 % w/w of TFLP respectively. Similarly the reduction in blood glucose level of aged mice were 8.58 % (p<0.05), 17.86 % (p<0.01) and 26.05 % (p<0.01) at the concentrations of 5, 10 & 15 % w/w of TFLP when compared to control group of aged mice.

Effect on Brain Malonaldehyde Level

The animals receiving the TFLP (5, 10 and 15 % w/w of diet) showed the significant decreased in the brain malonaldehyde level of both young and aged mice as compared to control group. The extent of reduction were 11.70 % (P<0.05), 33.45 % (p<0.01) and 46.46 % (p<0.01) of young mice at the concentration of 5, 10 & 15 % w/w of TFLP when compared to control group. In the aged mice, reduction were 13.77 % (p<0.05), 25.38 % (p<0.01) and 33.90 % (p<0.01) at 5, 10 & 15 % w/w respectively (Fig. 10).

Effect on Brain Reduced Glutathione Level

TFLP show a remarkable increase in brain reduced glutathione level in the young and aged mice. The percent decline in the reduced glutathione level were 9.89 % (p<0.05) at TFLP concentration of 5 % w/w of diet, 28.57 % (p<0.01) and 40.56 % (p<0.01) at TFLP concentration of 10 & 15 % w/w in young mice. In the aged mice percent reduction were 20.25 % (p<0.05), 37.97 % (p<0.01) & 40.50 % (p<0.01) at 5, 10 and 15 % w/w respectively (Fig. 11).
Fig. 9: Effect of TFLP (5, 10 and 15 % w/w) on blood glucose level of young and aged mice

Values are expressed as Mean ± SEM, (n=6). * & ■ denotes p < 0.05 when compared to control group of Young & aged mice. ** & ■ ■ denotes p < 0.01 when compared to control group of Young & aged mice. (One-way ANOVA followed by Dunnett’s t-test).
