ABSTRACT

Wound healing is a process that is fundamentally a connective tissue response.1 Healing process is a complicated biological process, which follows a definite pattern of cellular and molecular events which includes regeneration of parenchymal cells, migration and proliferation of both parenchymal cells and connective tissue cells, synthesis of extracellular matrix proteins, remodeling of connective tissue, collagenization and acquisition of wound strength.2,3,4 Fibroblasts are responsible for producing the new matrix needed to restore structure and function to the injured tissue. Fibroblasts attach to fibrin and integrin cables and begin to produce collagen, which then becomes cross-linked.5 The growing popularity of natural and herbal medications because of easy availability of raw materials, cost-effectiveness and paucity of reported adverse reaction, there is an upsurge in research for assessment of herbal drugs for wound healing ability.10 Vitex negundo Linn. [VN] (Verbenaceae) is a woody, aromatic shrub growing to a small tree which bears tri- or penta-foliate leaves.7 The crude aqueous extract of Vitex negundo Linn. leaves have been investigated for laxative activity.11 Leaves of VN have been reported for its anti-inflammatory activity, antihistaminic, membrane stabilizing and antioxidant activities.9 It has also been reported to have innumerable medicinal properties like analgesics, anticonvulsant, bronchial relaxant and hepatoprotective activity.10

So the present study was undertaken to investigate the in vivo wound healing activity of aqueous and ethanolic extracts of Vitex negundo leaves on rats using in vivo circular excision and linear incision wound models.

INTRODUCTION

Wound healing is a process which can be minor or major, needs to be given special attention for providing quick healing remedy. In the present study an attempt has been made to evaluate the wound healing potential of aqueous and ethanolic extracts of leaves of Vitex negundo. A rapid restoration of the wounded skin was observed with the application of both the extracts in circular excision and linear incision wound model in wistar rats. Particularly aqueous extract treated rats showed 98.53% and ethanolic extract showed 94.97% accelerated contraction of incision wound with an increase in the tensile strength in case of incision wound as compared to the standard reference drug, Cipladine. The wound healing parameters like Hydroxyproline, Collagen, and Hexosamine were estimated in regenerated skin which further solicits the potential of the leaves of Vitex negundo to heal experimentally induced wound.

Preparation of the plant extract

The leaves were cleaned and shade dried prior to extraction. The leaves obtained after drying were powdered and aqueous as well as ethanolic extraction was carried out using a Soxhlet apparatus. After 24 hours the extracts were concentrated in a rotavap under vacuum and stored at 4 to 8°C in refrigerator for further use.

Acute Dermal Toxicity Study

The acute dermal toxicity study was performed as per OECD guidelines no 424 on rats. The test extracts were uniformly applied on skin over an area which is approximately 10% of the total body surface area. The animals were observed for 14 days for any clinical signs such as redness, itching and oedema. It was observed that the dose was safe and lower dose was considered for further study.11

Animals

Wistar rats of both sexes of 150-200gm bodyweight were used for studying the wound healing activity of Vitex negundo. The animals were housed in National Toxicology Centre, Pune. A total of 48 animals were approved by the Institutional Animal Ethical Committee (IAEC) for National Toxicology Centre under the Research Project no 109 on 24/12/2010. The animals were given standard diet pellet and water ad libitum. The rats were kept at 12 hours light / dark cycle and maintained at 24 ± 2°C and optimum relative humidity.

Wound Healing Activity

Excision Wound Model

The rates of contraction of wound and epithelization were monitored in the Excision wounds model. Initially animals were anaesthetized with ketamine and xylazine 1:1 ratio and the back side of each rat was shaved. Excision wounds sized 300 ~ 400 mm² and 2 mm depth were made by cutting out layer of skin from the shaved area. In the Control Group animals the wound was left open12 whereas the standard drug cipladine13 and test drug applied topically on excision wound. The extracts were applied at a dose of 200 mg/kg/day for 16 days. Wound areas were measured on days 0, 3, 6, 9, 12 and 15 for all groups, using a transparency sheet and a permanent marker.14

Incision Wound

A linear paraxternal incision of 6 cm long was made through the full thickness of the skin. In each animal wound was closed with interrupted sutures, both the extracts were applied on the incision wounds daily for 14 days. However sutures were removed on the 10th day. Using Tensiometer the breaking strength of the wound in kilograms was measured on 15th post wounding day.15
Biochemical parameters

The circular wound area was excised at the end of the study. The biochemical parameters like collagen, hydroxyproline, and hexosamine levels were determined for evaluating the healing properties of both the extracts of *Vitex negundo* namely aqueous and ethanolic.

Statistical Analysis

Statistical analysis of the data using one way ANOVA for comparing the treated groups with that of untreated control group was done by Dunnett’s test using Graphpad Prism version 5. The data with P value <0.05 were considered to be statistically significant.

RESULTS

Circular Wound contraction

Control rats showed significant delayed contraction of the circular excised wound when compared with the standard drug cipladine treated animal as well as test drug treated animals (P < 0.05) Table 1. The aqueous extract of VN showed 98.52% wound contraction which was similar to standard drug which showed 98.39% contraction of wound. However, ethanolic extract showed 94.97% wound contraction at an interval of 15 days. Fig 1

Linear Incision wound

The effect of wound healing activity in this model was evaluated by determining the tensile strength of the incision wound of control group and standard as well as test drug treated group. The aqueous extract of VN showed significant increase in tensile strength (P < 0.05) as compared to the control group. (Fig 2)

Biochemical parameters for Wound Healing

Both the test extracts showed an increase in hydroxyproline, collagen and hexosamine levels per gram of dried tissue compared to control group indicating better effects of wound healing. (Table no. 2)

DISCUSSION

Wounds are physical injuries that result in an opening or breaking of the skin. According to the Ayurveda, Vrana (wounds or ulcers) is the discontinuation of lining membrane that after healing leaves a scar for life. Exogenous wounds could be a trauma, such as Chinna (cut wound), Bhinna (perforated wound), Viddha (punctured wound), Kshata (lacerated wound), Picchita (contusion), and Ghrista (abrasion wound).

Both aqueous and ethanolic extracts of Vitex negundo were evaluated for wound healing in Wistar rats which exhibited a strong promotion in healing of wound. In excision wound model it has been observed that, the wound area contraction rate was higher in aqueous extract treated animals than that of ethanolic extract of Vitex negundo. In addition to the reduction in wound size, the test group also showed a faster rate of healing and scar formation. In incision model the breaking strength is a fundamental parameter which was measured experimentally by the amount of force required to disrupt it. According to Gouthamchandra et al, 2010, initial stage of wound requires little breaking strength as the clot alone holds the edges which increases rapidly as collagen deposition increases and cross-linkages are formed between the collagen fibers.

It has been reported earlier that collagen synthesis rapidly increases in the wound area soon after an injury. The levels of collagen were determined from hydroxyproline content by the formula given by Neumann & Loga. Among the four groups the highest collagen content was found in the aqueous extract treated animals followed by Standard drug and Ethanolic Extract treated animals. Glycosaminoglycan chains are formed from repeating hexosamine units which supports various protein structures including collagen in the tissues. In our studies hexosamine content of the excised tissue in the test drug treated group showed an increase as compared to the standard and control untreated group.

From the present studies it was evident that Vitex negundo has significant wound healing activity which can be useful for establishments of lead compounds in wound healing activity.

ACKNOWLEDGEMENT

The authors are thankful to all NTC staff members for their valuable suggestions and help to carry out the research work.
