ABSTRACT
The present investigation was carried out to evaluate the antiinflammatory activity of ethanolic extract of leaves of Ipomoea staphylina and its ethyl acetate and n-butanol fractions in carrageenan induced paw oedema. In cotton-pellet induced granuloma model the extract and its fractions (200 mg/kg, p.o.) significantly (P<0.001) decreased the granuloma formation. The inhibitory effects of the ethanolic extract of leaves of Ipomoea staphylina and its ethyl acetate and n-butanol fractions on the production inflammatory cytokines tumor necrosis factor-alpha (TNF-α) was studied in a lipopolysaccharide (LPS) activated RAW 264.7 cell line. The ethanolic extract its fractions potently inhibited TNF-α. The viability of cells at different concentration (0-300 µg/ml) was unaffected as determined by the MTT cytotoxicity assay.

Keywords: Ipomoea staphylina, Anti-inflammatory, Carrageenan, Granuloma, Tumor necrosis factor-alpha (TNF-α), Lipopolysaccharide, Cytotoxicity.

INTRODUCTION

Inflammation is a local response of living mammalian tissues to the injury. It is a body defense reaction in order to eliminate or limit the spread of injurious agents. There are various components to an inflammatory reaction that can contribute to the associated symptoms and tissue injury. Oedema formation, leukocyte infiltration and granuloma formation represent such components of inflammation.

The treatment of inflammation is depends on nonsteroidal or steroidal anti-inflammatory agents. Nonsteroidal antiinflammatory drugs (NSAID) reduce the pain and inflammation by blocking the cyclooxygenase enzyme (COX) and thus the production of prostaglandin, but long-term administration of NSAID may induce gastrointestinal ulcers and renal disorders due to their non-selective inhibition of both isoforms of COX enzyme, the constitutive (COX-1) and the inducible (COX-2) isoforms. On other hand COX-2 inhibitors have been associated with cardiovascular side effects. Therefore, developing new agents with more potential antiinflammatory activities and with lesser side effects is, at present, of great interest.

Ipomoea staphylina is an extensive climber belonging to the family Convolvulaceae. A literature review reveals antinflammatory property of Ipomoea staphylina. Other species of genus Ipomoea like Ipomoea pes-caprae, Ipomoea imperati, Ipomoea involucrata and Ipomoea asarifolia has been reported for antinflammatory activity. So, the present study was carried out to evaluate the antiinflammatory activity of ethanolic extract and its ethyl acetate and n-butanol fractions of leaves of Ipomoea staphylina.

MATERIALS AND METHODS

Plant Material
Leaves of Ipomoea staphylina were collected from forest area of Karnataka near to Bangalore. The Ipomoea staphylina plant taxonomically identified and authenticated by Dr. K. Karthikeyan at Central National Herbarium, Botanic Garden, Howrah, where the voucher specimen is conserved under the reference number SMP-01. The leaves of Ipomoea staphylina were cleaned and dried under shade at room temperature for several days and powdered. The powder was defatted with petroleum ether (60-80 GR) for 72 h and then the dried powder was extracted with ethyl alcohol to get a yield of 10.2 % w/w. The ethanolic extract was dispersed in distilled water and partitioned with ethyl acetate in a separating funnel till the colourless ethyl acetate fraction is obtained. Then the aqueous part is then partitioned with n-butanol to get the butanol fraction. Ethyl acetate and butanol fraction so obtained was concentrated by keeping in boiling water bath to get the solid residue. The dried extracts were stored in airtight container and placed in refrigerator.

Drugs and chemicals
Carrageenan and lipopolysaccharide were purchased from Sigma Chemical Co. TNF-α assay kit from Amersham Bioscience, MTT Assay powder from SRL and Diclofenac was purchased from Micro Labs. All other chemicals used in this study were obtained commercially and were of analytical grade.

Experimental animals
In-bred wistar rats (150-200 g) of either sex were maintained under controlled conditions of temperature (23± 2 °C) and humidity (50 ± 5%) and a 12-hour light–dark cycle, were used for the experiment. They were housed in sanitised polyplypoxene cages containing sterile paddy husk as bedding. They had free access to standard rat pellet diet and water ad libitum. The animals were given a week's time to get acclimatized with the laboratory conditions. All the experimental procedures were performed according to the committee for the purpose of control and supervision of experiments on animals (CPCSEA), ministry of social justice and empowerment Government of India, norms and approved by the Institutional Animal Ethics Committee (IAEC).

Acute toxicity studies
Mice were kept overnight fasting prior to drug administration. Animals were received a single oral dose (2000 mg/kg, b.w.) of Ethanolic extract of leaves of Ipomoea staphylina and its ethyl acetate and n-butanol fractions. After the administration of Ipomoea staphylina leaves extract and its different fractions food was withheld for further 3-4 h. Animals were observed individually at least once during the first 30 min after dosing, periodically during the first 24 h (with special attention during the first 4 h) and daily thereafter for a period of 14 days. Once daily cage side observations included changes in skin and fur, eyes and mucous membrane (nasal) and also respiratory rate, circulatory (heart rate and blood pressure), autonomic (salivation, lacrimation, perspiration, piloerection, urinary incontinence, and defecation) and central nervous system (ptosis, drowsiness, gait, tremors and convolution) changes. Mortality, if any, was determined over a period of 2 weeks.

Carrageenan induced paw oedema
The antiinflammatory activity of ethanolic extract of leaves of Ipomoea staphylina its ethyl acetate and n-butanol fractions on carrageenan-induced paw oedema was determined. The animals were divided into eight groups consisting of six rats each. The control group received 2.5 ml/kg of saline, the standard group received diclofenac sodium at the dose of 10 mg/kg, p.o. and the test groups received the ethanolic extract of leaves of Ipomoea staphylina and its ethyl acetate and n-butanol fractions at the dose of 200
mg/kg, p.o and 100 mg/kg, p.o. Thirty minutes after administration of different substances, 0.1 ml of 1% of carrageenan subcutaneously into the planter region was injected to all animals in the left hind paw. The paw volume, up to the tibiotarsal articulation, was measured using plethysmometer (model 7150, Ugo Basile, Italy). The measures were determined at 0 h (before carrageenan injection) and 0.5 h, 1 h, 2 h, 3 h and 4 h later.

The percentage inhibition of inflammation was calculated using the formula:

\[
\text{Percentage Inhibition} = \frac{V_t - V_c}{V_c} \times 100
\]

Where \(V_t\) - Increase in paw volume in test animal

\(V_c\) - Increase in paw volume in control group.

The results obtained as mean increase in paw volume (ml) and percentage inhibition in paw oedema.

**Cotton pellet induced granuloma in Rats**

In cotton pellet induced granuloma method\(^{16}\) sterilized cotton pellet of 50mg were implanted beneath the abdominal skin in axilla or groin region of the rat through a single incision along the midline under anesthesia using pentobarbitone (40 mg/kg, i.p.). The animals were divided into eight groups consisting of six rats each. The control group received 2.5 ml/kg of saline, the standard group received diclofenac sodium at the dose of 1 mg/kg, p.o. and the test groups received the ethanolic extract of leaves of *Ipomoea stapylina* and its ethyl acetate and n-butanol fractions at the dose of 200 mg/kg, p.o and 100 mg/kg, p.o. The drugs were administered for 7 days. On the eighth day the animals were anesthetized with ether and the implanted cotton pellet with granulation tissue were removed and freed from extraneous tissues and dried in an oven at 60°C for 24 hours. The dried pellets were weighed and the gain in weight in each group was calculated. The difference in granulation tissue weight was noted. The increase in the granulation tissue weight of test and standard groups were compared with control group. The percentage inhibition was calculated by using the formula:

\[
\text{%) Inhibition} = \frac{W_c - W_d}{W_c} \times 100
\]

\(W_d\) = difference in pellet weight of the drug treated group

\(W_c\) = difference in pellet weight of the control group

**Cell Culture**

The mouse macrophage-like cell line, RAW 264.7, was purchased from the Korean Cell Line Bank (ATCC). RAW 264.7 cells were cultured in Roswell Park Memorial Institute medium (RPMI) containing 10% fetal bovine serum (FBS; GIBCO Inc., NY, USA) and 100 U/ml of penicillin/streptomycin. The cells were incubated at 37°C in a humidified, 5% CO\(_2\) atmosphere. To stimulate the cells, the control group received 2.5 ml/kg of saline, the standard group received diclofenac sodium at the dose of 1 μg/ml, and the test groups received the ethanolic extract of leaves of *Ipomoea stapylina* and its ethyl acetate and n-butanol fractions at the dose of 200 mg/kg, p.o. and 100 mg/kg, p.o. The drugs were administered for 7 days. For experimental studies, cells were grown to 80-90% confluency, harvested with 0.025% trypsin and 0.52mM EDTA in phosphate buffer saline and plated at desired density and allowed to reequilibrate for 24 h before any treatment. All experiments were conducted in RPMI with 10% FBS/FCG and 1% PSN. In the presence of DMSO (0.2% vehicle control) respectively, this concentration was non toxic for cells.

**MTT Assay**

Cell viability was determined by MTT [3-(4,5-Dimethyl thiazole-2-yl)-2,5-diphenyltetrazolium bromide] assay\(^{17}\). One type of cell lines – Raw 264.7 (Murine macrophage cell) were exposed to hydroxicom compounds p1 and p2 at different concentrations for 24-48 h. The assay was based on the ability of the mitochondrial dehydrogenase enzyme from viable cells to cleave the tetrazolium rings of pale yellow MTT and form a purple formazan crystal which is largely impermeable to the cell membrane thus resulting accumulation within living cell. After incubation of cells with MTT reagent for 2-4 hrs, a detergent solution containing 0.04N HCL, 80% absolute isopropanol and 20% Triton X, was added to lyse the cells so that the crystals were solubilised and purple color was added. Then the samples were read at a wavelength of 570 nm. The number of surviving cells is directly proportional to the level of formazan created which is proportional to the optical density of the sample.

**Measurement of cytokine production**

For the cytokine immunoassay, the cells (1×10\(^6\)/ml) were preincubated 1 h with MECO and further cultured 6 h with 1 μg/ml of LPS in 24-well plates. Supernatants were removed at the allotted times. TNF-α production was quantified by TNF assay kit (Amersham Bioscience). The following the manufacturer’s instructions. The kit is specific for TNF-α and does not measure other cytokines.

**Statistical analysis**

All data were represented as means±SEM. Results were statistically evaluated using one way analysis of variance (ANOVA) followed by Tukey-Kramer (post tests) using INSTAT software. P < 0.05 was considered as statistically significant.

**RESULTS**

In LD50 studies, it was found that the animals were safe up to a maximum dose of 200 mg/kg body weight. There were no changes in normal behaviour pattern and no signs and symptoms of toxicity and mortality were observed. The biological evaluation was carried out at doses of 100 and 200 mg/kg body weight.

The ethanolic extract of leaves of *Ipomoea stapylina* and its ethyl acetate and n-butanol fractions were evaluated for carrageenan induced paw oedema. The result obtained indicates that the ethanolic extract of leaves of *Ipomoea stapylina* (200 mg/kg, p.o.) significantly decreased the carrageenan induced paw oedema at 0.5 h (P<0.01), 1 h (P<0.01), 2 h (P<0.001) 3 h (P<0.001) and 4 h (P<0.001). The ethyl acetate fraction (200 mg/kg, p.o.) significantly decreased the paw oedema at 1 h, 2 h, 3 h and 4 h (P<0.001). The n-butanol fraction of *Ipomoea stapylina* (200 mg/kg, p.o.) also significantly decreased the formalin induced paw oedema at 1 h (P<0.005), 2 h (P<0.01), 3 h and 4 h (P<0.001). Maximum inhibition of paw oedema was observed with the ethanolic extract of leaves of *Ipomoea stapylina* and its ethyl acetate and n-butanol fractions (200 mg/kg, p.o.) at 4 h. Diclofenac sodium (10 mg/kg, p.o.) and the ethanolic extract of leaves of *Ipomoea stapylina* (200 mg/kg, p.o.) inhibited paw oedema by 46.72 % and 35.24 % respectively (Table 1).

In Cotton pellet induced granuloma the ethanolic extract of leaves of *Ipomoea stapylina* its ethyl acetate and n-butanol fractions were screened for cotton pellet induced granuloma in the rats (Table 3). The the ethanolic extract of leaves of *Ipomoea stapylina* its ethyl acetate and n-butanol fractions at the dose of 200 mg/kg, p.o and 100 mg/kg, p.o. significantly (P<0.001) decreased the granuloma formation. The the ethanolic extract of leaves of *Ipomoea stapylina* and its ethyl acetate and n-butanol fractions (200 mg/kg, p.o) showed 53.53%, 45.79% and 33.46% of inhibition of granuloma formation respectively, whereas the standard drug diclofenac sodium (10mg/kg, p.o) showed 47.66 % of inhibition of granuloma formation.

Cytotoxicity studies of ethanolic extract of leaves *Ipomoea staphylina* and its ethyl acetate fraction on RAW264.7 cells.

The MTT assay showed that up to a concentration of 300 µg/ml did not affect the cell viability at 48 h of incubation (Figure 1). Concentrations of the extract below the threshold were selected for further studies.

**DISCUSSIONS**

Carrageenan is the phlogistic agent of choice for testing anti-inflammatory drugs as it is not known to be antigenic and devoid of apparent systemic effect. It induces oedema in a biphasic response which is shown to be mediated by histamine and serotonin during the first hour. After which increased vascular permeability is maintained by the release of kinins up to 2.5 h, followed by the release of kinins and finally through the release of Bradykinin, prostaglandins and lysosomes from 2.5 to 6 h. The later phase is reported to be sensitive to most of the clinically effective anti-inflammatory agents. The mediators appear to be prostaglandins, the release of which is closely associated with migration of leucocytes into the inflamed site. The carrageenan induced paw edema model in rats is known to be sensitive to cyclo-oxygenase (COX) inhibitors and has been used to evaluate the effect of non-steroidal anti-inflammatory drugs (NSAIDs). This method was chosen for this study since it is the most prominent experimental model in search for new anti-inflammatory drugs and evaluation of anti-inflammatory effect of natural products. We found that the administration of the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions has an apparent anti-inflammatory activity.

The injection of carrageenan produces a typical biphasic oedema associated with the production of several inflammatory mediators such as histamine, serotonin, bradykinin, prostaglandins, nitric oxide, and cytokines. According to the result of our study, the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions were able to effectively inhibit the oedema in the later phases, suggesting that these compounds inhibit different chemical mediators of inflammation.

The cotton pellet-induced granuloma is widely used to assess the transudative and proliferative components of chronic inflammation. The weight of the wet cotton pellets correlates with transudate material and the weight of dry pellet correlates with the amount of granulomatous tissue. In the present study, administration of the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions (200 mg/kg, p.o.) has been observed to inhibit the weight of wet cotton pellet exhibited inhibition of granuloma. It is well known fact that diclofenac sodium act by inhibiting the prostaglandins synthesis at the late phases of inflammation. This effect may be due to the cellular migration to injured sites and accumulation of collagen, an important mucopolysaccharide. The proliferative phase of macrophages, neutrophils, fibroblast and collagen formation which were the basic source for granuloma formation. Decreasing granuloma tissue, prevention of occurring of the collagen fiber and suppression of mucopolysaccharids are indicators of the antiproliferative effect by NSAIDs. In view of this, results of present study demonstrate that the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions has potential to inhibit sub-acute inflammation probably due to interruption of the arachidonic acid metabolism or inhibition proliferative phase.

In order to validate the use of the *Ipomoea staphylina* as an anti-inflammatory compound, the effect of the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions on the production of pro-inflammatory cytokine like TNF-α in LPS stimulated RAW 264.7 cells was investigated by in vitro. Therefore, MTT assay was carried out to examine the cytotoxicity. The assay showed that the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions up to a concentration of 300 µg/ml did not affect the cell viability at 48 h of incubation. Macrophage plays a central role in defense mechanism by the nature of their phagocytic, cytotoxic and intracellular killing capability. Bacterial lipopolysaccharide (LPS) is a natural ligand for Toll-like receptor 4 (TLR4). Stimulation of macrophage by lipopolysaccharide (LPS) results in increased production of different inflammatory mediators. Bacterial lipopolysaccharide (LPS) interacts with a variety of cell types, including endothelial cells, smooth muscle cells, granulocytes, thrombocytes, and macrophages/monocytes. Lipopolysaccharide binds first to LPS binding protein and then to cell surface CD14, before it activates TLR4 signaling pathways, which induce the production of pro-inflammatory mediators such as TNF-α.

Inflammatory cytokines appear to be interlinked in a cascade, produced serially by cells during inflammatory response. Cumulative evidence indicates that an abnormality in the production or function of TNF-α play an essential role in inflammatory lesions (De Nardin, 2001). TNF-α and other inflammatory cytokines activate the inflammatory cells and cause the production of other inflammatory mediators, which in turn modulate the gene expression, DNA damage and cellular proliferation contributing to progression of various inflammatory disorder. TNF-α, also induce the activation of iNOS gene transcriptional factor and this resultant induced production of NO has been implicated for immunological and inflammatory diseases. Therefore, the cellular manipulation of production of TNF-α and other inflammatory cytokines is of importance for regulation of inflammatory response.

The present study showed that the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions possessed that inhibitory effect on these proinflammatory cytokine. These compounds suppressed the production of macrophage derived proinflammatory cytokines (TNF-α) in LPS stimulated RAW 264.7 cells in dose dependent manner.

Taken together in vivo and in vitro results suggested that the ethanolic extract of leaves of *Ipomoea staphylina* and its ethyl acetate and n-butanol fractions posses anti-inflammatory activities. The
