ABSTRACT

Three Acacia species from south India, Acacia catechu, Acacia lycophloea and Acacia nilotica were taken for comparative phytochemical analysis. The chemical pattern of three species was compared using thin layer chromatography. The physico chemical parameters of each extract were analysed. TLC method was standardized using epicatechin as marker compound. Total tannins of all the species were determined spectrophotometrically. Gas Chromatographic analysis was carried out in n-hexane cold macerated leaf extracts of three species and compared the volatile constituents.

Keywords: Acacia, TLC, GC, Total tannins.

INTRODUCTION

Medicinal plants and plant- derived medicines are widely used in traditional cultures all over the world and they are becoming increasingly popular in modern society as natural alternatives to synthetic chemical1. Nearly all cultures from ancient times have used plants as a source of medicine. The World Health Organization (WHO) has listed 21,000 plants worldwide, reported used plants as a source of medicine. The World Health Organization (WHO) has listed 21,000 plants worldwide, reported

Chemical and chromatographic techniques can be used to aid in identification of an herbal material or extract. Chromatographic technique such as HPLC, TLC, GC and spectroscopic methods such as IR and UV-may also is used for fingerprinting. Markers compounds may be used to identify herbal materials, set specifications for raw materials, standardize botanical preparations during all aspects of manufacturing processes and obtain stability profiles. Acacia is the second largest genus in the Leguminosae family, comprising more than 1200 species. This species contains variety of bioactive components such as phenolic acids, alkaloids, Terpenes, tannins and flavonoids which are responsible for numerous biological and pharmacological properties.

MATERIALS AND METHODS

Preparation of Plant Extract

10 g of dried stem bark of each, Acacia catechu, Acacia lycophloea and Acacia nilotica was taken and suspended in 100 ml of 50% aqueous ethanol solution and subjected extraction by refluxing. The aqueous alcoholic extract obtained was filtered and the process was repeated for four days. The resulting filtrates were pooled for further processing. This pooled aqueous ethanolic extract was concentrated to 50 ml on rotavapour and it is taken for the study. 5 g of fresh leaf of all the species were cold macerated separately with n-hexane for Gas Chromatographic analysis.

Determination of Physico chemical Parameters

Qualitative analysis for Physico chemical Parameters were carried out in triplicate according to prescribed standard methods in Indian Pharmacopeia. Estimation of Total Tannins

100 mg of tannic acid was dissolved in 100 ml of distilled water. 1 ml of this solution was diluted into 100 ml in distilled water to give 10 µg/ml tannic acid solutions.

A series of calibrated 10 ml volumetric flask were taken and working standards of 5- 45 µg solutions were taken. To each flask 0.5 ml Folin-Denis reagent and 1 ml sodium carbonate solution were added, the volume is made up to 10 ml by distilled water. The solution without tannic acid was used as blank. The blue colored complex thus produced is measured at 775 nm.

1 ml of each extract is made up to 10 ml in similar manner. From the calibration curve the corresponding concentration of tannins were calculated. It was expressed as gram equivalent of Tannic acid.

Thin layer chromatographic profile

TLC of all extracts with epicatechin as marker was carried out on a pre-coated silica gel 60F254 TLC plate (Merck India) using toluene, ethyl acetate and formic acid as mobile phase in the ratio of 5:2:1. The plate was developed over a distance of 9 cm and visualized under visible light after spraying with Anisaldehyde sulphuric acid reagent followed by heating at 105 °C for 5 minutes.

Gas Chromatographic analysis

The cold macerated n-hexane extract was subjected to GC analysis on Agilent 6890 network GC, with a HP-5 column and Flame Ionisation Detector (FID). The injector temperature was set at 80 °C and that of detector was 220 °C. The temperature of the column was programmed as 0-5, 5-15, 100 °C (held 5 minutes), 15-25, 120 °C with an increase of 5°C per ramp.

RESULTS AND DISCUSSION

The physico chemical parameters such as water soluble extractive, alcohol soluble extractive, total ash, acid insoluble ash and water soluble ash were calculated (Table 1). The water soluble extractive was found to be 22-25% (W/V) for Ac catechu, 19-21% for Anilotica and total 23-25 % for A. lycophloea. The water soluble extractive and alcohol soluble extractive were found to be more for Anilotica. The alcoholic soluble extractive is less compared to water soluble extractive. The Por of water extracts vary from 6.2 to 6.6.

The total tannin is expressed in mg equivalent of Tannic acid per gram of extract (Fig. 1.1).The highest tannin content was found in Anilotica (0.18 mg E TA/ g) The thin layer chromatographic profile

showed the comparative chemical pattern of three species (Fig 1.2). The TLC tracks 1 is epicatechin, 2, 3 and 4 correspond to \textit{A. lucophloea}, \textit{Anilotica}, and \textit{Acatechu} respectively. Epicatechin is present both in \textit{Anilotica} and \textit{Acatechu} but it is absent in \textit{A. lucophloea}. \textit{Acacia nilotica} and \textit{Acatechu} showed almost similar chemical profile.

The physicochemical parameters, quantitative analysis and TLC Finger print can be used for quality evaluation of the selected Acacia species. The distinguishing bands in TLC Profile and the presence of marker compound epicatechin may be used as marker parameters for the Quality standardisation.

ACKNOWLEDGMENT
The authors are thankful to Vice chancellor, Karpagam University Coimbatore, Management of Arya Vaidya Sala Kottakkal for providing facilities for doing this work and to TATA Trust Mumbai for financial support.
