ABSTRACT

The antimicrobial activity of the methanolic leaf extract of Semecarpus anacardium L. was evaluated against medically important bacteria Staphylococcus epidermidis (ATCC 12228), Micrococcus luteus (ATCC10240), Methicillin-resistant Staphylococcus aureus (Hospital-isolate), Propionibacterium acnes (MTCC 1951) and yeast, Malassezia furfur (MTCC 1374) using the MIC and MBC/MFC analysis. The lowest MIC and MBC values were obtained for Staphylococcus epidermidis which was 100 mg/mL. The methanolic leaf extracts were subjected to evaluation for antioxidant activity by DPPH free radical scavenging method and Nitric oxide radical scavenging method. Using DPPH method, IC50 values for methanolic leaf extract was 91.65 ± 2.14 μg/mL and for ascorbic acid was found to be less than 20 μg/mL respectively. IC50 values for methanolic leaf extract and ascorbic acid was found to be 51.33 ± 2.00 μg /ml and 36.81 ± 2.06 μg /ml respectively using Nitric oxide radical scavenging method. The antioxidant activity of these extracts can be attributed to the presence of tannins, saponins and flavonoids.

INTRODUCTION

Despite the huge number of antimicrobial agents for various purposes that already exist, the search for new drugs is a continuous task since the target microorganisms often develop new genetic variants which subsequently become resistant to available antimicrobial agents and the effective lifespan of any antibiotic is thus limited. The world’s attention is now increasingly directed towards plant sources for developing antimicrobial drugs, since natural products are considered safer than synthetic ones. According to the World Health Organization, medicinal plants would be the best source to obtain a variety of drugs. Therefore, such plants should be investigated to better understand their properties, safety and efficacy [1]. There are several published reports describing the antimicrobial activity of various crude plant extracts [2,3]. Semecarpus anacardium is a deciduous tree belonging to Anacardiaceae family and is growing in tropical and temperate regions of south east asian countries. Its seed, commonly known as ‘marking nut’ is largely used in Indian traditional medicine ‘Ayurveda’ for the treatment of rheumatoid arthritis, gout and other inflammatory diseases, tumours, asthma, epilepsy, psoriasis and leprosy [4]. A wide spectrum of physiological activities including anti-inflammatory [5], antiarthritic [6]and anticancer [7] properties have been attributed to the seed and its preparations. In our previous preliminary phytochemical studies, the leaves of Semecarpus anacardium showed the presence of alkaloids, saponins, tannins, flavonoids, steroids, glycosides, hexose sugars, diterpenes, mucilages and gums [8].

Although, many studies have been done on Semecarpus anacardium, none of them were performed on the methanolic extract of leaf part of the plant against Staphylococcus epidermidis (ATCC 12228), Micrococcus luteus (ATCC10240), Methicillin-resistant Staphylococcus aureus (Hospital isolate), Propionibacterium acnes (MTCC 1951) and Malassezia furfur (MTCC 1374). Staphylococcus epidermidis is Gram-positive which is not usually pathogenic but patients with compromised immune systems are often at risk for developing an infection. These infections can be both nosocomial or community acquired, but they pose a greater threat to hospital patients [9]. Micrococcus luteus is Gram-positive. It may occasionally be opportunistic pathogen which can cause septic shock, pneumonia and urinary tract infections in an immune-deficient person [10]. Methicillin-resistant Staphylococcus aureus (Hospital isolate) is a Gram-positive bacterium responsible for several difficult-to-treat infections in humans. It is also called multidrug-resistant Staphylococcus aureus. MRSA is especially troublesome in hospitals and nursing homes, where patients with open wounds, invasive devices, and weakened immune systems are at greater risk of infection than the general public [11]. Malassezia furfur is the causative agent of Pityriasis versicolor, Pityriasis folliculitis and it has recently been implicated as a causative agent of seborrhoeic dermatitis and droppruff. It is a lipophilic yeast, therefore in vitro growth must be stimulated by natural oils or other fatty substances. The most common method used is to overlay Sabouraud’s dextrose agar containing cycloheximide (actidione) with olive oil or alternatively to use a more specialized media like Dixon’s agar which contains glycerol mono-oleate (a suitable substrate for growth) [12]. In the proposed work use of Sabouraud’s agar with Corn oil and Tween 80 has been made for Malassezia furfur. Propionibacterium acnes is the relatively slow growing, typically aerotolerant anaerobic, Gram-positive bacterium (rod) linked to the skin condition acne, it can also cause chronic blepharitis and endophthalmitis, the latter particularly following intraocular surgery [13].

Antioxidants are important in preventing human diseases. Naturally occurring antioxidants in leafy vegetables and seeds such as ascorbic acid, vitamin E and phenolic compounds possess the ability to reduce oxidative damage associated with diseases like cancer, diabetes, arthritis, cardiovascular diseases, cataracts and ageing[14-16]. Antioxidant compounds may function as free radical scavengers, reducing agents and quenchers of singlet oxygen species [17]. Synthetic antioxidants like butylated hydroxytoluene (BHT) and butylated hydroxyanisole (BHA) have restricted use in foods as they are carcinogenic. Therefore need of natural antioxidant has increased in recent years. The antioxidant activity in the leaf of Semecarpus anacardium was evaluated using DPPH and Nitric oxide radical scavenging activity.

MATERIALS AND METHODS

Plant collection and authentication

The leaves of Semecarpus anacardium were collected from an open field around Mumbai, Maharashtra. The identification of the plant was done at the Blatter Herbarium, St. Xavier’s College, Mumbai. The
plant specimen matches with the Blatter Herbarium specimen no.T-472 of S. C. Tavakari. Leaves were shade dried and made into coarse powder with mechanical grinder and then passed through sieve, B.S.S Mesh No.60.

**Instrument and chemicals**

Jasco V-630 spectrophotometer was used for the measurement of absorbances of solution mixtures. Standard used was Ascorbic acid (S.D Fine Chemicals, Mumbai), 2,2-diphenyl-1-picrylhydrazyl radical (DPPH) (Sigma Aldrich, Germany), Sodium nitroprusside (Fisher scientific, Mumbai), Sulphanilamide (S.D Fine Chemicals, Mumbai), N(1-Naphthyl) ethylene diamine dihydrochloride (S.D Fine Chemicals, Mumbai), DMSO (Himedia, India), Soyabean Casein Digest Agar medium (Himedia, India), Sabouraud’s agar (Himedia, India), Tween 80 (Himedia, India), Tryptone soy broth (TSB) (Himedia, India), HiAnera Gas Pack (Himedia India), Equitron Anaerobic jar.

**Preparation of the plant extract**

The leaf powder of *Semecarpus anacardium* (20 gm) was extracted with 250 ml methanol by soxhlet extraction for 8 hrs. The extract was concentrated on water bath at 60°C. The obtained dark brown thick liquid was stored in a glass vial in refrigerator.

**Bacterial strains**

Four bacterial strains, namely *Staphylococcus epidermidis* (ATCC 12228), *Micrococcus luteus* (ATCC10240), Methicillin-resistant *Staphylococcus aureus* (MTCC 1951) and yeast, *Malassezia furfur* (MTCC 1374) were used for antibacterial testing. The microbial isolates were procured from National Chemical Laboratories (NCL), Pune, Maharashtra, India and Microbial Type Culture Collection (MTCC) Chandigarh, India. The microorganisms were maintained at 4°C temperature.

**Determination of Minimum Inhibitory Concentration (MIC) and Minimum Bactericidal and Fungicidal Concentration (MBC / MFC)**

Determination of the minimum inhibitory concentration (MIC) was carried out only on leaves using the Broth dilution method [18,19] with slight modification. The extracts were reconstituted in 10% v/v aqueous dimethyl sulfoxide (DMSO) at the concentration of 1600 mg/ml. A serial two fold dilution of reconstituted extract was performed to obtain 800, 400, 200, 100, 50, 25, 12.5, 6.25, 3.125, 1.562, 0.781, 0.391, 0.195 mg/ml concentrations. Then 100 µl of an 18 hrs old culture of each of the bacteria earlier adjusted at 10^{5} Colony Forming Unit per milliliter (CFU/ml) was added to all tubes and thoroughly vortexed. The tubes were incubated at 37°C for 48 hrs and observed for growth in form of turbidity. The test tubes with the lowest dilution with no detectable growth by visual inspection was considered as MIC.

The MBC / MFC tube was determined by spot inoculating of bacterial suspension from the MIC tubes that did not show any growth and subcultured onto Soyabean casein digest agar plates and incubated at 37°C for 48 hrs for *S. epidermidis*, *M. luteus*, MRSA. For *M. furfur* Sabouraud’s agar with 0.2% corn oil and 0.5% tween 80 was used and the incubation period was 37°C for 72 hrs. For *P. acnes* media used was Tryptone soy broth (TSB) and the incubation period was 7 days at 37°C under anaerobic conditions. After incubation, the concentration at which no visible growth was seen on the agar plate was recorded as MBC / MFC.

**DPPH Scavenging Activity**

The free radical scavenging activity of the methanolic leaf extract of *Semecarpus anacardium* was measured in terms of hydrogen donating or radical scavenging ability using the stable radical DPPH (2, 2-diphenyl-2-picrylhydrazyl), 0.1 mM of DPPH in methanol was prepared.

Different concentrations of sample and standard used were 20, 40, 60, 80, 100, 200, 500, 1000 mg/ml After 30 minutes the absorbance was measured at 517 nm. Ascorbic acid was used as the standard. Lower absorbance of the reaction mixture indicated higher free radical scavenging activity [20,21]. Radical scavenging activity was expressed as inhibition percentage of free radical by the sample and was calculated using following formula:

\[
\% \text{ DPPH Scavenged} = \frac{A_{\text{Control}} - A_{\text{Sample}}}{A_{\text{Control}}} \times 100
\]

Where, \(A_{\text{Control}}\) was the absorbance of control (Methanol and DPPH).

A graph is plotted using % Inhibition v/s Concentrations (Table 2 & Fig 1 & 2).

**Nitric oxide Scavenging Activity**

The chemical source of Nitric oxide was sodium nitroprusside (10mM) in phosphate buffer (pH 7.4), which spontaneously generates nitric oxide. Nitric oxide interacts with oxygen to produce stable products, leading to the production of nitrates. 0.5 ml of 10mM sodium nitroprusside in phosphate buffer was mixed with 2 ml of different concentrations (20, 40, 60, 80, 100, 200, 500, 1000µg/ml) of the sample and standard and incubated at room temperature for 150 mins. After 150 mins the samples from the above were reacted with 1.2 ml Greiss reagent (1gm sulphanilamide in 5 ml ortho phosphoric acid and 104 mg N-(1-naphthyl) ethylene diamine dihydrochloride in 100 ml of distilled water. The absorbance of the chromophore formed during the diazotization of nitrite with sulphanilamide and subsequent coupling with N-(1-naphthyl) ethylenediamine was read at 546 nm. The reaction mixture without plant extracts but with methanol and sodium nitroprusside served as control. Ascorbic acid was used as positive control [22,23]. The results of anti-oxidant activity of methanolic extracts using Nitric oxide radical scavenging method were shown below (Table 3 and Fig 3 & 4).

The capability to scavenge the NO radical was calculated using the following equation:

\[
\% \text{ NO Scavenged} = \frac{A_{\text{Control}} - A_{\text{Sample}}}{A_{\text{Control}}} \times 100
\]

Where, \(A_{\text{Control}}\) is the absorbance of the control (Methanol and Sodium nitroprusside), \(A_{\text{Sample}}\) is the absorbance in the presence of the extracts. The antioxidant activity of the extracts were expressed as IC_{50}.

**RESULTS**

The minimum inhibitory concentrations of the methanolic leaf extract of *Semecarpus anacardium* on the selected microorganisms are shown in Table 1. The MIC values were tested from 800 to 0.195 mg/ml. *S. epidermidis* showed MIC and MBC values at 100 mg/ml whereas for *M. luteus* it was 100 and 400 mg/ml. MRSA showed a higher MIC at 400 mg/ml and MBC at 800 mg/ml. *P. acnes* showed MIC at 400 mg/ml and MFC at 400 mg/ml.

Using the DPPH scavenging activity, the IC_{50} value of methanolic leaf extract of *Semecarpus anacardium* was found to be 916.58 ± 2.14 µg/ml and for standard ascorbic acid it was less than 20 µg/ml respectively. By using Nitric oxide scavenging activity of methanolic leaf extract of *Semecarpus anacardium*, the IC_{50} value was found to be 51.33 ± 2.00 µg/ml and for standard ascorbic acid was 36.81 ± 2.06 µg/ml respectively.

DISCUSSION

Preliminary phytochemical studies revealed the presence of alkaloids, glycosides, tannins, flavonoids, steroids, phenols, proteins, hexose sugars, diterpenes, nonreducing polysaccharides, mucilages and gums and in the methanolic leaf extract of *Semecarpus anacardium* [8].

Earlier studies reported that the MBC values can either be the same or higher than the corresponding MIC values [24] which was proven in this study for *S. epidermidis*, the MIC was same as the MBC value (100 mg/ml). Higher MIC and MBC values were seen for *P. acnes* at 800 mg/ml under anaerobic conditions. For *M. luteus*, MIC was observed at 100 mg/ml while for MRSA, MIC was at 200 mg/ml with MBC value 2 times the MIC value (400 mg/ml). The yeast *M. furfur*, showed MIC and MFC both at 400 mg/ml. The MBC / MFC values which are obtained after plating various dilutions of the extracts are more reliable than the MIC values, obtained using turbidity as a measure of growth. Lower MIC and MBC values indicate higher efficacy [25].

Thus, the low MIC and MBC values exhibited by the leaf extract against *Staphylococcus epidermidis* is of potential importance in the health care delivery system, since it could be used as an alternative to orthodox antibiotics in the treatment of infectious diseases caused by these microbes, especially as they frequently develop resistance to known antibiotics [26].

The values of DPPH scavenging activity of methanolic extract are given in Table 2. From the analysis we can interpret that the effect of extract DPPH radicals increased with concentrations.

The measurement of the scavenging activity of DPPH radical allows one to determine exclusively the intrinsic ability of the antioxidant compound to donate hydrogen atoms or electrons to this reactive species in a homogenous system. The DPPH radical contains an odd electron which is responsible for the absorbance at 517 nm and also for the visible deep color. When DPPH accepts an electron donated by an antioxidant compound, the DPPH is decolorized which can be quantitatively measured from the changes in absorbance. Higher reduction of DPPH is related to the high scavenging activity performed by particular sample.

**CONCLUSION**

Bacterial infections can be treated with the *Semecarpus anacardium* leaf extract, since it exhibited favorable antibacterial and antifungal activity. The leaf of *Semecarpus anacardium* has never been evaluated for antibacterial activity against *Staphylococcus epidermidis*, *Micrococcus luteus*, *MRSA*, *Propionibacterium acnes* and *Malassezia furfur* before. Also it is for the first time a detailed study has been undertaken to demonstrate that the methanolic *Semecarpus anacardium* leaf extract can effectively scavenge various reactive oxygen species or free radicals under in vitro conditions. This may be due to a number of stabilized oxidation products that it can form after oxidation or radical scavenging. Hence, this plant can be used to discover new bioactive natural products that may serve as lead in the development of new pharmaceuticals.
