ABSTRACT
Objective: Aim of this work was to evaluate the antioxidant properties of the edible mushroom species, Lentinula edodes.

Methods: Presence of potential antioxidant compounds, such as, ascorbic acid, β carotene, lycopene, phenolics and flavonoids were tested. To understand the antioxidant potentiality like scavenging of superoxide radical, chelating of ferrous ion, scavenging capacity of DPPH radicals and reducing power of the extract were investigated.

Results: The extraction yield achieved from L. edodes extraction was 2.4%. Total phenolic content was 25.5 mg GAE/g and total flavonoids content was 2 mg CE/g. The EC50 value for superoxide radical scavenging activity was found to be at a concentration of 0.64 mg/ml.

Conclusion: The results obtained reveal that L. edodes can be a potential source of natural antioxidant which may be used to treat various oxidative stress related diseases.

Keywords: Ascorbic acid, edible mushroom, Lentinula edodes, flavonoids, phenols, reactive oxygen species

INTRODUCTION
Different biochemical reactions in our body generate free radicals and these are capable of damaging crucial biomolecules. Over-production of reactive oxygen species results in increase of oxidative stress and if they are not effectively neutralized by oxidative stress defence system, they lead to the development of diseases conditions in our body [1]. Every organism is equipped with defence system against oxidative damage but they often fail short, thus making the search for external antioxidants increasingly important. Antioxidants can protect human body from damages caused by reactive oxygen species. Although synthetic antioxidants are available in the market, their use is being restricted due to reported carcinogenicity and hepatotoxicity. Thus, in recent times antioxidants from natural sources are being sought extensively [1].

Mushrooms have been a part of human diet, for time immemorial and are well known for its nutritional and medicinal values. Recently, mushrooms have become attractive as functional food and as a source of physiologically beneficial medicine, while being devoid of unstable side effects [2]. Mushrooms are rich in different biologically active compounds like phenolics, tocopherol, lycopene, β-carotene etc. [1]. Recent investigations of different wild edible mushrooms from India have shown their potentiality for treatment of cancer [3-5], diabetes [6], ulcer [7], hepatic [8-11], cardio-vascular diseases [12], microbial pathogens [13-16], immunomodulation [17-19] etc. Here, an attempt has been made to evaluate the free radical scavenging activity of ethanolic extract of Lentinula edodes using various in vitro assay models.

MATERIAL AND METHODS
Preparation of extract
Ethanolic extract of the sample was prepared following Dasgupta et al. 2013 [20]. The sample was dried, powdered and extracted with ethanol at 25°C for 2 days. After filtration, the residue was then re-extracted with ethanol, as described above. Precipitate was discarded by centrifugation and the supernatant was concentrated under reduced pressure in a rotary evaporator. Then, this ethanolic extract of Lentinula edodes was stored at 4°C until further analysis. The percentage yield extracts were calculated based on dry weight as:

\[ \text{Yield} \% = \frac{(W_1 \times 100)}{W_2} \]

Where: \( W_1 \) = weight of extract after solvent evaporation; \( W_2 \) = Weight of the minced mushroom.

Determination of total phenolic content
The method for determination of phenol was performed following by Singleton and Rossi, 1965 [21]. To the sample extract (100 µl), 1 ml of 1N Folin-Ciocalteu reagent was added. After 3 min, a saturated sodium carbonate solution (approximately 35 g/100 ml, 1 ml) was added to it. The absorbance of the reaction mixture was measured at 725 nm after incubation for 1 hr 30 min at room temperature. Gallic acid was used as a standard, and the results were expressed as milligram gallic acid equivalent (mg GAE)/g of extract.

Determination of flavonoids
The flavonoid content was estimated following the method of Park et al. 1997 [22] 100µl of the sample extract was added to 80% ethanol containing 0.1ml of 10% aluminium nitrate and 0.1 ml of 1M potassium acetate. The mixture was incubated at room temperature for 40 min and its absorbance was measured at 415 nm. Quercetin was used as standard.

Determination of β-carotene and lycopene
β-carotene and lycopene determination was done by Nagata and Yamashita, 1992 [23]. 100µl of the sample extract was vigorously shaken with 10 ml of an acetone–hexane mixture (4:6) for 1 min and filtered through Whatman No. 4 filter paper. The absorbance of the filtrate was measured at 453, 505, and 663 nm. β-carotene and lycopene content were calculated according to the following equations:

\[ \text{Lycopene (mg/100 ml)} = \frac{0.0458 \times A_{505} + 0.372 \times A_{505} - 0.0806 \times A_{453}}{1} \]

\[ \text{β-carotene (mg/100 ml)} = \frac{0.216 \times A_{453} - 0.304 \times A_{505} + 0.452 \times A_{453}}{1} \]
The results were expressed as mg of carotenoid/g of extract.

**Determination of ascorbic acid content**

Ascorbic acid content was determined by a method followed by Rekhla et al. 2012 [24], with few relevant modifications. Standard ascorbic acid (100 μg/ml) was taken in a conical flask and made up to 10 ml by 0.6% oxalic acid. It was titrated with 2, 6-dichlorophenol indophenol dye. The amount of dye consumed (V, ml) was equivalent to the amount of ascorbic acid. Similarly the sample (w μg/ml) was titrated with the dye (V, ml). The amount of ascorbic acid was calculated using the formula:

\[
\text{Ascorbic acid (μg/mg)} = \frac{[(10 \text{ μg/ml}) \times V_{\text{ml}}] \times w \text{ μg}}{1000}
\]

**DPPH radical scavenging assay**

The model of scavenging DPPH radical is a widely used method to evaluate antioxidant activities in a relatively short time as compared with other methods. Effect of antioxidants on DPPH scavenging was thought to result from their hydrogen donating ability. Upon reduction, solution of DPPH fades from purple to yellow. Thus, a lower absorbance at 517 nm indicates a higher radical scavenging activity of extract. The DPPH radical scavenging ability of the sample extract was measured according to Shimada et al. 1992 [25]. 2ml of reaction mixture was prepared using different concentrations of sample [1-2.5 mg/ml] and methanol solution of DPPH (0.004%) (w/v). The absorbance was read against methanol as blank at 517 nm after 30 min incubation at room temperature in dark. The degree of scavenging was calculated by the following equation:

\[
\text{Scavenging effect (%) = } \frac{(\alpha_0 - \alpha_1)}{\alpha_0} \times 100
\]

Where \(\alpha_0\) and \(\alpha_1\) were the absorbance of control and in presence of sample.

**Chelating ability**

Ferrozine can react with \(\text{Fe}^{2+}\) to form violet complex. When there is other chelating agent, the ferrozine-\(\text{Fe}^{2+}\) formation is disrupted with decrease in colour of the complex. Therefore, measurement of absorption of the reaction mixture at 562 nm could be used to estimate the metal chelating activity of an antioxidant. To measure the ferrous ion chelating ability of the sample the method proposed by Dinis et al. 1994 [26] was followed with little modification. The sample was mixed with 2ml FeCl\(_3\) (0.5 ml) to which 5mM ferrozine was added. The mixture was shaken vigorously and left to stand at room temperature for 10 min. The absorbance was measured at 562 nm. The decrease in absorbance indicated an increase in the ferrous ion chelating ability of the sample. The following formula was used for determination of the percentage inhibition of ferrozin \(\text{Fe}^{2+}\), complex formation:

\[
\text{Scavenging effect (%) = } \frac{(\alpha_0 - \alpha_1)}{\alpha_0} \times 100
\]

Where \(\alpha_0\) and \(\alpha_1\) were the absorbance of control and in presence of sample.

**Reducing power**

Reducing power of the sample was determined following Oyaizu 1986 [27]. Varied concentration of the sample (0.5-2 mg/ml) were added to 2.5 ml of 0.2 M phosphate buffer (pH 6.6) and 2.5 ml of 1% potassium ferrocyanide. 2.5 ml of 10% trichloro acetic acid was added to the mixture after an incubation of 20 min. It was then centrifuged for 10 min at 12000 rpm. 2.5 ml of the supernatant was mixed with distilled water and 0.5 ml of 1% ferric chloride. Its absorbance was interpreted as an increase in reducing power of the sample. Antioxidants have ability to donate electrons and cause conversion of \(\text{Fe}^{3+}\) in ferric chloride to ferrous \(\text{Fe}^{2+}\). Resulting Perl’s Prussian blue is measured at 700 nm and higher absorbance indicates higher reducing power.

**Superoxide radical scavenging activity**

The riboflavin – light – nitroblue tetrazolium (NBT) system as suggested by Martinez et al. 2001 [20] was used to study the superoxide radical scavenging activity of the ethanolic extract of \(L.\) edodes. This method was followed with minor modification. 3 ml of reaction mixture was prepared containing 50 mM sodium phosphate buffer (pH 7.8) 13 mM methionine and ethanolic extracts of various concentrations, 75 μM NBT, 100 μM EDTA and 2 μM riboflavin. One set of the reaction mixture was kept exposed to light for 10 min to activate the NBT and absorbance of each mixture was measured at 560 nm against identical mixtures from another set kept in the dark for same duration. BHA (Butylated hydroxyanisole) was used as standard. The degree of scavenging was calculated as follows:

\[
\text{Scavenging effect (%) = } \frac{(\alpha_0 - \alpha_1)}{\alpha_0} \times 100
\]

Where \(\alpha_0\) and \(\alpha_1\) were the absorbances of control and in presence of sample.

**Determination of total antioxidant capacity (TAC)**

The TAC was determined on the basis of reduction of Mo (VI) to Mo (V) by the antioxidant compound and the formation of green phosphate/Mo (V) complex at acidic pH. Total antioxidant capacity of the sample was investigated and compared against ascorbic acid. The TAC of the sample was determined by the assay prescribed by Preito et al. 1999 [29] with modifications. A reaction mixture was prepared consisting of 0.3 ml of reagent solution (0.6 M H\(_2\)SO\(_4\), 28 mM Na\(_2\)SO\(_4\), 4mM NH\(_4\)MoO\(_4\)). Absorbance was measured at 695 nm after heating tubes at 95°C for 90 min. Ascorbic acid was used to draw a standard curve and TAC was expressed as the equivalent of ascorbic acid.

**Statistical analysis**

Results were subjected to statistical analysis using Student’s t test. Values are mean ± SD of 3 replications.

**RESULTS AND DISCUSSION**

In the present study, ethanolic fraction from fruiting bodies of \(L.\) edodes was successfully isolated and physicochemical parameters were documented. Measurement of antioxidant properties of \(L.\) edodes showed relatively high antioxidant activity. Extractive value and bioactive components of ethanolic fraction of \(L.\) edodes were recorded.

The extract was brown in colour, sticky in nature and had extractive value of 10 ± 0.55%.

**Phytochemicals assay**

Naturally occurring antioxidant components including phenols, flavonoids, \(\beta\)-carotene, lycopene and ascorbic acid were found in ethanolic extract of \(L.\) edodes. Total phenol being the major naturally occurring antioxidant components was found as 25.5 μg gallic acid equivalent/mg of extract. Ethanolic extract of \(L.\) edodes also contained flavonoid as 2 ± 0.025 μg quercetin equivalent/mg of extract. Very negligible amount of \(\beta\)-carotene and lycopene were found such as 0.015 ± 0.002 μg/mg and 0.01 ± 0.002 μg/mg of the extract respectively. Ascorbic acid was also found (1.9 ± 0.06 μg/mg of extract) in small quantities.

Phenolic compounds possess scavenging ability due to their hydroxyl groups and are known to be powerful antioxidant. In the present study, the total phenolic content of \(L.\) edodes was found higher than \(Pleurostus ostreatus\) [30] and \(Pleurostus citrinopileatus\) [31] which were reported to be 5.49 μg/mg and 8.62 μg/mg respectively and similar to that of \(Pleurostus squarrosulus\) 18.1 μg/mg [32]. The phenolic content was also found to be comparatively higher than that of \(Russula albonigra\) (9.53 μg/mg) as reported [33].

**DPPH radical scavenging assay**

The model of scavenging DPPH radical is a widely used method to evaluate antioxidant activities in a relatively short time compared with other methods. Effect of antioxidants on DPPH scavenging was thought to result from their hydrogen donating ability. DPPH is a stable organic nitrogen radical and accepts an electron or hydrogen to become stable diamagnetic radical. Upon reduction, solution of DPPH fades from purple to yellow. Thus, a lower absorbance at 517 nm indicates a higher radical scavenging activity of extract. As shown in figure 1, ethanolic extract of \(L.\) edodes
exhibited the radical scavenging activity at the rate of 21.86%, 57.11%, 72.72% at 0.1, 0.3 and 0.5 mg/ml concentrations respectively (EC<sub>50</sub> 0.283 ± 0.007 mg/ml). This activity was much better than <i>Amanita vaginata</i> which had EC<sub>50</sub> at a concentration of 1.48 mg/ml [34].

The ability of extract to donate electrons can be evaluated using the reducing power assay. Ferrous ion has the capacity to reduce oxygen to superoxide radical and generation of hydroxyl radical from hydrogen peroxide. In presence of the extract reductive ability of Fe<sup>2+</sup> to Fe<sup>2+</sup> transformations was investigated. The reducing capacity of analysed mushroom extract may serve as the indicator of its potential antioxidant activity.

In reducing power assay, yellow colour of the test solution changes to various shades of green to blue as the reducing power of sample increases. Antioxidant has ability of donation of electron and causes conversion of the oxidation form of iron (Fe<sup>3+</sup>) in ferric chloride to ferrous (Fe<sup>2+</sup>). Resulting Perl’s Prussian blue is measured at 700 nm and higher absorbance indicates higher reducing power. Figure 3 reveals the reducing power of ethanolic extract of <i>L. edodes</i>, as a function of their concentration. EC<sub>50</sub> value was at the concentration of 0.45 ± 0.2 mg/ml which was much less than that of <i>Amanita vaginata</i> (0.91 mg/ml) [34].

In ethanol or water solution, ferrozine can react with Fe<sup>3+</sup> to form violet complex. When there is other chelating agent, the ferrozine-Fe<sup>3+</sup> formation is disrupted with decrease in colour of the complex. Therefore, measurement of absorption value of reaction mixture at 562 nm could be used to estimate the metal chelating activity of antioxidant. Figure 2 reveals that the ethanolic extract of <i>L. edodes</i> demonstrated a marked capacity for iron binding ability which showed a dose dependent response. 50% chelation was found at a concentration of 0.85 ± 0.05 mg/ml. EDTA exhibited excellent chelating ability of about 97% at these concentrations. In previous studies, it was showed that the EC<sub>50</sub> value of the ethanolic extract for <i>Russula delica</i> [35] was more than 3 mg/ml which is much higher than that of the sample of our study. So, <i>L. edodes</i> could be considered as a good metal ion chelating agent.

![Fig 1: DPPH scavenging activity of ethanolic extract of L edodes.](image1.png)

<sup>Fig 1: DPPH scavenging activity of ethanolic extract of <i>L. edodes</i>. (Values are the mean ± standard deviation of three separate experiments, each in triplicate)</sup>

**Chelating ability of ferrous ions**

Transition metals e.g. Fe<sup>2+</sup>, Cu<sup>2+</sup>, Pb<sup>2+</sup>, Co<sup>2+</sup> may serve as catalysts for the initial formation of radicals. Chelating agents has ability to stabilize transition metals in living systems and inhibit generation of free radicals. Development of potential chelating agents from natural mushrooms, thus provides an effective way to protect human beings from free radical damage.

In ethanol or water solution, ferrozine can react with Fe<sup>3+</sup> to form violet complex. When there is other chelating agent, the ferrozine-Fe<sup>3+</sup> formation is disrupted with decrease in colour of the complex. Therefore, measurement of absorption value of reaction mixture at 562 nm could be used to estimate the metal chelating activity of antioxidant. Figure 2 reveals that the ethanolic extract of <i>L. edodes</i> demonstrated a marked capacity for iron binding ability which showed a dose dependent response. 50% chelation was found at a concentration of 0.85 ± 0.05 mg/ml. EDTA exhibited excellent chelating ability of about 97% at these concentrations. In previous studies, it was showed that the EC<sub>50</sub> value of the ethanolic extract for <i>Russula delica</i> [35] was more than 3 mg/ml which is much higher than that of the sample of our study. So, <i>L. edodes</i> could be considered as a good metal ion chelating agent.

**Determination of reducing power**

The ability of extract to donate electrons can be evaluated using the reducing power assay. Ferrous ion has the capacity to reduce oxygen to superoxide radical and generation of hydroxyl radical from hydrogen peroxide. In presence of the extract reductive ability of Fe<sup>2+</sup> to Fe<sup>2+</sup> transformations was investigated. The reducing capacity of analysed mushroom extract may serve as the indicator of its potential antioxidant activity.

In reducing power assay, yellow colour of the test solution changes to various shades of green to blue as the reducing power of sample increases. Antioxidant has ability of donation of electron and causes conversion of the oxidation form of iron (Fe<sup>3+</sup>) in ferric chloride to ferrous (Fe<sup>2+</sup>). Resulting Perl’s Prussian blue is measured at 700 nm and higher absorbance indicates higher reducing power. Figure 3 reveals the reducing power of ethanolic extract of <i>L. edodes</i>, as a function of their concentration. EC<sub>50</sub> value was at the concentration of 0.45 ± 0.2 mg/ml which was much less than that of <i>Amanita vaginata</i> (0.91 mg/ml) [34].

![Fig 3: Reducing power of ethanolic extract of L edodes.](image3.png)

<sup>Fig 3: Reducing power of ethanolic extract of <i>L. edodes</i>. (Values are the mean ± standard deviation of three separate experiments, each in triplicate)</sup>

**Superoxide radical scavenging assay**

The method used by Martinez et al. [19] is based on generation of superoxide radical by auto-oxidation of riboflavin which in turn reduces yellow dye NBT to produce blue formazon in presence of light. Decrease in absorbance at 560 nm with antioxidants designates the consumption of superoxide anion. In the present study, ethanolic extract of <i>L. edodes</i> was found to be a notable scavenger of superoxide radicals (Fig.4) (EC<sub>50</sub> 0.283 ± 0.007 mg/ml) and showed comparable scavenging activity with BHA (EC<sub>50</sub> 0.34 ± 0.01 mg/ml). The action may depend on hydrogen atom donation by its components leading to the formation of secondary stabilized radical species.

![Fig 4: Superoxide radical scavenging activity of ethanolic extract of L edodes.](image4.png)

Determination of total antioxidant capacity (TAC)

Phosphomolybdenum method is a good method for evaluation of total antioxidant capacity. The method is based on reduction of Mo (VI) to Mo (V) by the antioxidant compound and the formation of green phosphate/Mo (V) complex at acidic pH. Total antioxidant capacity of ethanolic extract of \textit{L. edodes} was investigated and compared against ascorbic acid. The extract showed 276 ± 24 µg/mg ascorbic acid equivalent antioxidant capacity.

**EC50 values**

The ethanolic fraction of \textit{L. edodes} showed good antioxidant activity by \textit{in vitro} assays like reducing power, ferrous ion chelating, superoxide radical scavenging activity and DPPH radical scavenging activity along with some amount of total phenol, flavonoids, β carotene, lycopene and ascorbic acid (Fig. 5).

**CONCLUSION**

The data recorded in the above experiments showed that the ethanolic fraction of \textit{Lentinula edodes} has a good antioxidant property and free radical scavenging power, which might be good sources for the development of antioxidant food additives. Phenolic component mostly polyphenols, flavonoids seemed to be responsible for the antioxidant activity. So, the ethanolic fraction of \textit{Lentinula edodes} could be used as a possible food supplement or in pharmaceutical industry.
