## ABSTRACT

Increased connectivity and remote monitoring and control mechanisms have revolutionized the field of measurement and automation. The proposed work is to design a system which will integrate a mobile bot with Arduino, and it is also possible with LabVIEW through a gateway to run wirelessly. An autonomous robot vehicle is to travel from source to destination through the wheels which are controlled by processor. This will be helpful launch in the application where human being travel will be difficult to meet the work. The proposed system will be able to follow a path with obstacle avoiding. Further, the vehicle can be integrated with NI instruments and with LabVIEW to make it autonomous. LabVIEW is a graphical programming language gives a platform for the engineers, which is effective and scalable to focus on robotics neglecting the minute implementation details.

**Keywords:** Arduino Uno board, Motor driver, Hardware in loop, Software in loop, Object recognition, Ethernet networks.

## INTRODUCTION

Recent years' wireless technology making all the things automated and working with internet, which is motivating the students to learn about robotics and work in the field of automation. Wireless mobot that is wireless autonomous robot, which is used in artificial intelligence research dominating in the market. Hence, in recent years' research is going in wireless mobots. They are so many platforms by which we can design wireless robots using C, C++, and Java. Working of the system depends on the operation of the ultrasonic sensors employed to avoid collision with unwanted obstacles. The two DC motors connect to vehicle will get a signal from the Arduino Uno. The main moto of developing this system will be helpful in the field where human entry will be difficult to trace and to monitor the path. The prime objectives that are associated with installing of robotic system in industries are: To enhance the quality and efficiency, to reduce the labors, to demand huge demand in the market, and to work in harsh environment also. Hence, the microcontrollers will provide a better way to sort these problems. It is also possible to build using LabVIEW. LabVIEW is having the ability to generate, control, and acquire the data; hence, any non-programmer can use LabVIEW to develop their ideas without writing thousands of codes.

LabVIEW is a graphical programming platform which will include front panel and block diagram. Along with LabVIEW platform, NI modules are used for connectivity and for monitoring purpose. NI modules such as gateway and wireless sensor network (WSN) will be used to make the system more flexible for commercial application. Gateway will connect the LabVIEW to WSN which is placed on vehicle. LabVIEW and vision assistant module can be used for image processing and feature extraction which will play an important role in traffic monitoring and security purpose. Since the LabVIEW provides a compressive and scalable platform which will make the design, prototypes and deployment phases, allowing designer to focus the automation by ignoring minute implementation details.

## LITERATURE SURVEY

An ArgiBot will able to perform agricultural processes such as seeding, spraying of chemicals, weeding. ArgiBot is controlled by Arduino Mega board with AT Mega 2560 microcontroller [1]. Along with Arduino Raspberry Pi a mini-computer is interfaced to monitor and control the

operation of the robot. The Arduino placed on the bot and the robot will be able to move in any direction. Sensors are placed along with body which will show the depth of the path, and there is a mechanism for plantation and the information will be delivered to next robot using Wi-Fi. The system is not so strong to work in complex field, and range of communication range between the robots will be small. Saraladevi and Sedhumadhavan [2] proposed autonomous four-wheeled robot using Arduino, which will start moving from source to destination point by finding the path, avoiding the obstacle and video streaming. All the parameters will be achieved by Wi-Fi technology avoiding the Bluetooth module. Path is identified by the aggrandized genetic algorithm which is best. Here, they failed to communication range for long distance. Amer *et al.* [3] developed a two-wheeled robot which is compact and portable with an Arduino which is focused on collision detection, avoidance, and avoid to fall from height using Wi-Fi and Bluetooth module.

A mobile vehicle made by Ugurlu [4] using LabVIEW and embedded hardware. He developed a remote-controlled robot and an autonomous robot using arm processor, and monitoring is done at LabVIEW. The main idea behind this was to explore about the usage of hardware and LabVIEW. He presented Coron robot and luminary microrobot which are based on Arm cortex-M3. Fang and Duan [5] presented system which will identify and extract the features of moving vehicles in LabVIEW. The moto behind their work is to automatically generate and maintain a representation of the background, which can be later used to classify the background and foreground to identify the vehicle. They used the tools available from NI-like NI assistant modules, and in LabVIEW, they kept observation of vehicles. All the concepts are meant to explore the system automatically to for one or other application based on the LabVIEW instead of using other available programming languages.

Changalasetty *et al.* [6] developed obstacle detection for intelligent robots based on LabVIEW and laser measurement system. Obstacle detection is important in the field of automation and sensing surrounding environment.

They implemented the system with the help of LabVIEW and LMS291 sensor to detect the obstacle. The LabVIEW and LMS291 interfaced with the help of RS232 serial communication port. Graphical user

HC SR04 is the ultrasonic sensor used in this model. Ultrasonic distance measuring module which will provide 2- 400 cm non-contact distance sensing action. The accuracy of the sensor is up to 2 mm. Operating voltages are 5 V DC and operating current is 15 mA. The operating frequency is 40 Hz, and the measuring angle is 15° (Fig. 3).

**WORKING**

Fig. 4 shows the block diagram will illustrate about how the component is interfaced with Arduino to form complete system. In the diagram, Arduino is acting as central part by which all the peripherals are controlled and monitored. All the connections are made according to the circuit diagram. Fig. 5 is setup of the proposed concept.

Fig. 5 shows the data flow diagram clearly depicts the working flow of wireless mobot.

When the robot starts moving, the ultrasonic sensor will continuously detect the presence of the object and then calculates the distance between the robot and reflective surface. The information will be processed by the Arduino microcontroller board. The calculated

distance is compared with threshold distance mentioned to avoid collision. The rotation will be continued when the distance is greater than the threshold distance. This will be continued along the path and robot keeps on moving with avoiding collision. This robot will move in the prescribed path when the objects come it will stop, and it will go around the object and settles in the same path (Figs. 6 and 7).

**RESULTS**

As mentioned in the working procedure, the robot will detect the obstacle whose distance falls below the threshold distance, based on this movement of wheels will go to take place. Figs. 8 and 9 will show the output obtained from the ultrasonic sensor. Through the signals, we can analyze the presence and absence of obstacle. Here, the time interval between the robot and obstacle will be converted to equivalent distance in terms of centimeter or inches.

The standard formula for distance calculation is as follows,  $Inches = Duration / 74 / 2$  and  $Cm = Duration / 29 / 2$ . Robot will move and stop based on the threshold distance set to avoid the collision with obstacles.

**CONCLUSION AND FUTURE WORK**

The moto of the project is to study the entire design and working of the wireless robot, interfacing of the sensors and other peripherals to the microcontroller, and also programming the Arduino. The

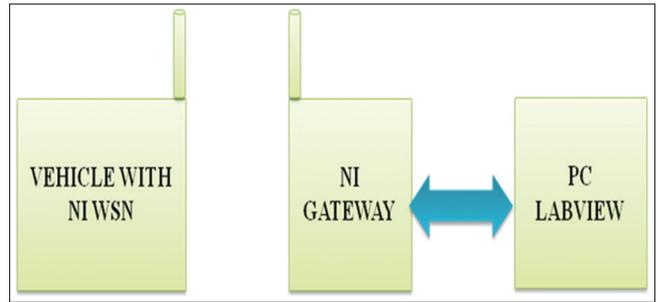

Fig. 10: Block diagram

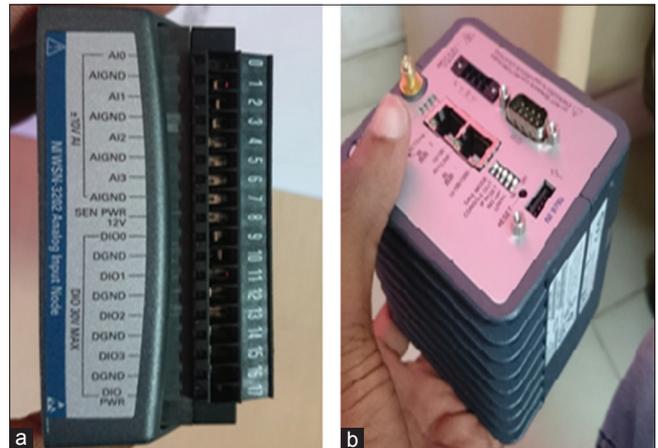

Fig. 11: NI modules (a) NI WSN 3212 module, (b) NI gateway 9792

output is obtained in Phase I of this stage as expected, where the vehicle tracked the path and also the obstacle avoiding mechanism is met. The system can be made accurate by adding more artificial intelligence to it. Future work that is Phase II will include the design of the robot using NI instruments and LabVIEW. The designed robot can also be controlled using Wi-Fi or Bluetooth module to make it much more effective.

**Future work**

The proposed entire system can be designed using NI modules, which will provide a more efficient real-time module. The below block diagram will show the connection between different components of NI modules with LabVIEW. LabVIEW will provide huge accelerated productivity, rapid prototyping, and scalability for the system (Fig. 10).

**NI WSN 3212**

In the proposed system, NI WSN 3212 is used which is a four channel and 24 bit thermocouple input device which is more sensitive for the analog inputs. It is low power device which will work with gateway to form WSN. We can connect the sourcing digital output to NI WSN 3212 in either drive high only mode or drive high/low mode. There are so many WSN available from the NI which is specific for application. All these work with lower bandwidth range (Fig. 11a).

**NI gateway 9792**

Gateways are called protocol converters which can operate at any network layer. Any servers which will be acting as gateway are called as proxy server and firewall server. Gateway will contain devices such as protocol.

Translators, impedance matching devices, rate converters, and signal translators which are necessary to provide system interoperability. NI gateway 9792 has serial port RS-232 to which we can connect the devices (Fig. 11b).

**Applications**

Wireless robot can be used in navigation system; household purpose such as vacuum cleaning with much more added artificial intelligence to the proposed system, these kinds of vehicles can be installed in dangerous environment where the human entry is impossible.
