ABSTRACT

The present investigation was to study the compression ignition (CI) engines with cottonseed biodiesel along with different percentage of exhaust gas recirculation (EGR) for analyzing the emission characteristics. In this experiment, the EGR percentage was varied from 0% to 30% in a four-stroke, air-cooled, single cylinder, diesel engine capable of developing 4.4 kW-rated power to study its emission characteristics, which were clearly compared with diesel fuel. From the experiment, it is observed that the increase in EGR percentage in fresh mixture which intern resulted in reduction in oxides of nitrogen emissions. The maximum percentage reduction in oxides of nitrogen, when compared to neat diesel operation, is 65.06%. Even though there is an increase in carbon monoxide and hydrocarbon emission for various EGR rate.

Keywords: Emission characteristics, Alternate fuels, Cottonseed oil, NOx emission.

INTRODUCTION

Compression ignition (CI) engines are most widely used in heavy-duty vehicles. Commonly used fuel for CI engine is diesel. Diesel has increasing demand among developing countries like India due to increasing in a number of automobiles. Important considerations to look up with performance and emission characteristics of diesel engines are emissions of carbon monoxide (CO), hydrocarbon (HC), CO₂, NOₓ, and smoke opacity. Since diesel engines reported for high emission rates and environmental impacts, alternative fuels have been suggested to blend with diesel. A lot of researches have been conducted in CI engines, and various engine parameters are analyzed by employing with biodiesel. Diesel engine will release more amount of oxides of nitrogen and smoke emissions. In recent, researchers are focusing on reducing the emissions of oxides of nitrogen and smoke. This research work particularly focuses exhaust gas recirculation (EGR) technique to reduce the emission of oxides of nitrogen in diesel engine.

A recent study carried out by researchers revealed that 25% of cars and trucks are causing about 90% of air pollution throughout the world. One of the major contributors is passenger vehicles which account for greater amounts of nitrogen oxides, CO, and other pollution. In 2015, about half of the nitrogen oxides and CO and one-fourth of the hydrocarbons emitted by automobiles into the air. Burning fuel in an engine gives the power to move a car. Pollution produced from the cars comes from by-products of this combustion process (exhaust) and also from evaporation of the fuel itself.

Nature has made two things available, one is carbon, and another one is hydrogen. Both petrol and diesel fuels contain hydrogen and carbon atoms. In an ideal engine, oxygen present in the air would converts all the carbon present in the fuel to carbon dioxide and all the hydrogen present in the fuel to water. However, nitrogen present in the air would remain unchanged. The combustion process cannot be ideal in practical and tends to emit various types of pollutants. The most common types of exhaust pollutants are nitrogen oxide, hydrocarbons, CO, and carbon dioxide.

Emissions due to combustion have been minimized by changing the quality of fuels. Biodiesel is the better alternative to both gasoline and diesel fuels. Biodiesel can be employed in engine either directly or can be blended with diesel fuel. Biodiesel results in greater amount of reduction in emissions of CO, nitrogen oxides, particulate matters, and sulfates compared to gasoline and diesel fuels. Biodiesel when blended with diesel fuel, reductions in emissions are directly proportional to the amount of biodiesel present in the blend. Biodiesel is usually preferred as it is safer to handle than diesel fuel due to its low volatility.

In general, biodiesel feedstock extracted from several types of agricultural crops. This contributes greater significant benefits to farmers and farming communities. Cottonseed oil is one of the important vegetable oils which have a greater possibility of using as biodiesel because of its good lubricating properties. A lot of researches done an implementing cottonseed oil as a biodiesel and one of which concluded that the possibility of CO emission happens due to the presence of vegetable oil content in the fuel [1]. Furthermore, CO and HC emissions are more for cottonseed oil blended with methanol than hippo oil blended with methanol [2]. It was reported that smoke opacity rate reduces sufficiently and NOx emission rates increase marginally in preheated cottonseed oil and diesel mixture compared to the neat mixture of cottonseed oil [3]. This study showed that CO and HC emissions are lower in all the biodiesel blends compared to mineral diesel [4]. In this study, biodiesel blends show higher NOx rates than diesel as it is mainly due to high O₂ content and high temperature in cylinders [5]. This study showed that autoignition is retarded due to increase in EGR ratio and results in combustion for longer period and also results in decrease in absolute heat release rate [6]. In this study, it was showed that cooled EGR tends to increase in emission levels of CO and HC, and at the same time, there is a significant reduction in NOx emission rates.[7] This study reveals the investigation of pilot injection strategy effects on combustion and emission characteristics of diesel engine with medium EGR rate and showed that increase in the level of CO and HC emission levels [8]. It was concluded that spark timing could be advanced by 8 crank angle degrees with addition of 12% EGR and also it reduces fuel consumption up to 4.1% at 7.0 bar IMEP [9]. This study showed that change in EGR has significant effects on indicated thermal efficiency and also emission levels of CO, NOx, and HC. EGR change also causes variation in fuel properties and oxygenated structures [10]. It was reported that change in EGR reduces mean charge temperature and NOx emissions reduce at higher percentage of EGR and at the same time increase HC and CO emission levels [11]. In this study, it was
stated that 20% increase in EGR reduces NOx emission rates up to more than 65% with increase in HC and CO emission levels [12]. This study revealed the increasing trend in NOx emissions with increasing biodiesel ratio in the fuel blend [13]. This study showed that the use of biofuel blends is certainly beneficial as it experiences NOx emission increase with increase in the percentage of biodiesel in the blend, while PM, CO, and HC decreased with increase in the percentage of biodiesel in the blend [14]. In this study, it was reported that CO and CO$_2$ emission rates were considerably reduced with the increase in load for biodiesels compared to petro diesel [8]. This study showed that there was a sufficient reduction in CO and CO$_2$ emission characteristics for all the biodiesels than ordinary diesel [15]. This study highlights the decreasing trend in CO and HC emissions with increasing load for all biofuel blends compared to diesel fuel, and average NOx emissions are higher for the former [16]. In this study, for all compression ratios (CR), CO and HC emission rates with biodiesels are lower than that of diesel fuel [17]. This study suggested that biodiesel made with a fish oil as a good option as it has good emission characteristics such as low CO emission, low PM and smoke opacity, and high NOX rates [18]. In this study, 20% of polanga blends shows the highest brake thermal efficiency (BTE) for all the injection timings [19]. This study showed that NOx increased marginally with the increase in the percentage of mahua (biodiesel) in the blends and could be safely blended with 20% of diesel used as a suitable alternative fuel for diesel [20]. In this study, except NOx, the other emission characteristics such as HC, CO, and CO$_2$ are sufficiently decreased due to preheating of the fuel [21]. This study showed that significant reduction in NOx and smoke emissions achieved with fuel consumption about 12% higher when compared to ordinary diesel using EGR technique [22]. In this study, there occurs a reduction in smoke levels and NOx emissions in premixed gasohol and ethanol-fueled diesel when compared to direct injected diesel fuel [23]. This study concluded that smoke levels are reduced in cottonseed oil and neem oil blends when compared to conventional diesel [24]. In this study, it was stated that CO and hydrocarbons emission rates reduced in greater amounts in cottonseed oil blends with orange peel when compared with conventional gasoline [25]. This study showed that all the emission levels on the biodiesel are comparatively less when compared to conventional diesel fuel and concluded that orange peel and cottonseed oil are more optimum compared to diesel [26].

### Experimental Setup

A direct injection, single cylinder, and four-stroke cycle diesel engine of 662 cm$^3$ of displacement is used as the test engine. Kistler pressure transducer was used to measure the cylinder pressure.

The sensing element consists of a metal diaphragm, which deflects under pressure. This deflection is a converted voltage signal, which is proportional to the cylinder pressure. The charge amplifier further amplifies the voltage signal from the pressure transducer. The crank position is determined using crank angle encoder. The encoder pulse and cylinder pressure signal are fed into the data acquisition system. The port fuel injector is mounted on the intake port for achieving homogeneous charge.

### Experimental Procedure

The total fuel consumption for diesel and biodiesel for various EGR rate. COX, UHC, and CO emissions will be measured using an exhaust gas analyzer. The smoke intensity will be measured using Bosch smoke meter. The test engine will be maintained at a speed of 1500 rpm throughout the experiments. Finally, the biodiesel results were compared with neat diesel for validation.

### Uncertainty Analysis

All physical quantity measurements are usually tended to produce uncertainties. Uncertainty analysis or error analysis is usually carried out to check accuracy in experiments. Root mean square method was used to get the magnitude of error and realistic error limits for the computed results.

The uncertainty in the computed values such as BTE, brake power, and flow measurements of fuel was estimated. The uncertainties in the measured parameters, voltage ($\Delta V$) and current ($\Delta I$), estimated by the Gaussian method, are $\pm$3 V and $\pm$0.14 A, respectively. For fuel time ($\Delta t$) and fuel volume ($\Delta t_r$), the uncertainties are taken as $\pm$0.2 s and $\pm$0.1 cc/s, respectively.

1. Temperature measurement

Uncertainty in temperature is $\pm$1% (T>150°C), $\pm$2% (150°C<T<250°C), and $\pm$3% (T<250°C).

2. Percentage of uncertainty for the measurement of speed, mass flow rate, NOx, hydrocarbon, smoke, and pressure are given as follows:

1. Speed: 1.1
2. Mass flow rate of air: 1.3
3. Mass flow rate of diesel: 1.0
4. NOx: 1.1
5. Hydrocarbon: 0.01
6. CO: 0.8

### Results and Discussion

#### CO Emission

CO is an in-between product in the combustion of hydrocarbons. It is formed as a result of insufficient combustion, which is attenuated by a lack of oxidants, temperature, and residence time. Some of the carbon in the fuel ends up as CO due to lack of O$_2$ required for oxidation. Even at sufficient oxygen level, dissociation caused by high peak temperatures.

During the expansion stroke, dissociated CO may freeze. Maximum CO emission usually occurs during engine startup when the engine is in condition to withstand poor fuel evaporation. The percentage of CO of cottonseed oil was lower than diesel fuel at no load conditions. This was because better combustion took place in the engine fueled with cottonseed oil fuel. However, the level of CO emission rate gradually increases for cottonseed oil. At maximum load, cottonseed oil emits 33.3% higher CO rate than diesel fuel.

**HC emissions**

High HC emission rate occurs as a result of over mixing of fuel and air beyond lean flammability limits during delay period and also due to undermixing of fuel injected toward the end of injection process, resulting in rich air-fuel ratios for complete combustion.

At maximum load, cottonseed oil emits 23.6% higher CO rate than diesel fuel. This can be mainly due to the higher viscosity of cottonseed oil than diesel fuel. This clearly states that there will be no possibility of uniform distribution with air, resulting in bigger fuel droplets.

**Oxides of nitrogen emissions**

NOx is formed as a result of a combination of nitrogen and oxygen from the air under heat and pressure. More heat and pressure give you more NOx. The main reason for higher NOx production in diesel combustion is the temperature and duration of the combustion flame due to a burning of mixed fuel and air. Due to increase in applied load on the engine, emission of NOx rate increases. At maximum load, diesel emits 7.56 % higher NOx than cottonseed oil. To minimize the NOx emitting rate further, EGR technique is employed with cottonseed oil as a fuel. EGR is an engine conditioning technique to control NOx which works by re-circulating a portion of an engine’s exhaust gas back to the cylinders of engines. This tends to decrease the amount of excess oxygen during combustion period. This gives better result in a reduction of NOx rate to a minimal level. EGR 10%, 20%, and 30% emit level of NOx rate, namely, 41.7 %, 93.2%, and 97% less than of NOx emitted by diesel.

**CONCLUSION**

In this experimental analysis, it has confirmed that cottonseed oil with EGR can be used as a better alternative to diesel as it has better emission characteristics. The following conclusions are drawn based on the experimental results.

- NOx emission for CSO fueled engine is 929 ppm and 1005 ppm for diesel-fueled engine. The increase in NOx emission rate in diesel than the preheated CSO is mainly due to higher combustion temperature.
- CO and hydrocarbon emissions are higher for CSO-fueled engine than diesel-fueled engine due to insufficient combustion.
- To control higher NOx emission rates in diesel-fueled engine, the engine controlling technique known as EGR technique is employed with CSO.
- EGR gives greater results such as EGR 10%, 20%, and 30% which emit a level of NOx rate, namely, 41.7 %, 93.2%, and 97% less than of NOx emitted by diesel.
