OBJECTIVE: Topiramate is an antiepileptic drug (AED) used for the treatment of partial seizure in adult and children epilepsy patients. It passed through the placenta causing a birth defect. However, little literature focused on placental alteration due to the administration of topiramate during pregnancy. So, applying different predictive parameters; placental weight, histopathological (Haematoxylin and Eosin), histochemical (periodic acid Schiff's) and immunohistochemistry (Caspase-3).

METHODS: Topiramate was orally administrated to the pregnant rats with dose 100 mg/kg rats from 5th to 19th day of gestation. The dam's undergone hysterecotomy and the placentae were weighted and stained by Haematoxylin and Eosin, periodic acid Schiff's and Caspase-3.

RESULTS: The study indicated that there is statistically significant (P<0.05) increase in the treated placental weight (0.4717±0.03788) compared with control group (0.5208±0.02930). Also, the light microscopic examination of the placental specimens using Haematoxylin and Eosin staining revealed that an alteration in both basal and labyrinth zone. Apoptotic feature in spongiotrophoblast and trophoblasts is detected. Positive Periodic acid Schiff's reaction for polysaccharides in the topiramate-treated group. Caspase-3 is showing apoptotic cells in the trophoblast layer.

CONCLUSION: Long-term daily use of topiramate during pregnancy can lead to obvious pathological histotoxic effects in layers of placenta tissues which may be implicated in cognitive affection. Various effects of topiramate necessitate further investigations.

KEYWORDS: Caspase-3, Periodic acid Schiff's, Placenta, Topiramate
Caspases, such as Caspase-3, -6 and -7, which were responsible for degradation of cellular proteins [18].

To detect the glycogen content in the placenta, the histochemical staining was applied; Periodic acid Schiff's to identify poly-saccharides.

However, there are no much available reports concerning topiramate teratogenic potential in humans. This could be explained by a limited number of pregnancies exposed. Very few reports available are on animal experimentation with controversial results. Therefore, topiramate was selected in this study to evaluate its effects, if any, on the placenta.

**MATERIALS AND METHODS**

**Drug used**

Topiramate tablet (100 mg) is used in the treatment of obesity; migraine prevention; fibromyalgia; diabetic peripheral neuropathy; seizure prevention. It was purchased from Kahira pharmaceutical company, Cairo, Egypt. Each tablet contains 100 mg of topiramate.

**Animal housing**

Virgin female and male albino rats, *Rattus norvegicus*, weighing about 170-180g were used in the present investigation. The animals were obtained from the animal house of the Faculty of Veterinary Medicine, Giza, Egypt. Before starting the experiment, animals were allowed to acclimatize for at least 7 d. Pregnancy was established by housing females in the pro-estrous and oestrous stages with healthy fertile males overnight; 12-h light/dark cycle (2:1) under controlled housing females in the pro-estrous and oestrous stages with healthy fertile males overnight; 12-h light/dark cycle (2:1) under controlled temperature (25±2 °C), humidity (60±20%) and given feed and water ad libitum. The next morning, females with a positive vaginal plug or vaginal smears were considered pregnant, and the day of detection was defined as the first day of pregnancy or gestation [19, 20]. Experimental protocols and procedures used in this study were approved by the Cairo University, Faculty of Science, and Institutional Animal Care and Use Committee (IACUC) (Egypt). The animals were handled according to the Guide for the Care and Use of Laboratory Animals, 8th Edition (2011 National Academies Press).

**Experimental design and animal treatment**

Pregnant rats were divided into two groups (12 per group). The control group received tap water, and the experimental groups received 100 mg/kg of topiramate diluted in tap water. The dosing regimen was based on human therapeutic dose (HED). Treatments were administered orally by gavage from day 5 up to 19 of pregnancy, weighing about 170-180g were used in the present investigation. The animals were obtained from the animal house of the Faculty of Veterinary Medicine, Giza, Egypt. Before starting the experiment, animals were allowed to acclimatize for at least 7 d. Pregnancy was established by housing females in the pro-estrous and oestrous stages with healthy fertile males overnight; 12-h light/dark cycle (2:1) under controlled temperature (25±2 °C), humidity (60±20%) and given feed and water ad libitum. The next morning, females with a positive vaginal plug or vaginal smears were considered pregnant, and the day of detection was defined as the first day of pregnancy or gestation [19, 20]. Experimental protocols and procedures used in this study were approved by the Cairo University, Faculty of Science, and Institutional Animal Care and Use Committee (IACUC) (Egypt). The animals were handled according to the Guide for the Care and Use of Laboratory Animals, 8th Edition (2011 National Academies Press).

**Histopathological studies**

Placenta of the control and treated groups were firstly fixed for histological investigation by light microscopy using: 10% formalin solution for 24 h. washing was done in running water to remove excess fixative then dehydration using serial ascending series of ethyl alcohol. Specimens were cleared in xylene and embedded in paraffin wax at 56 degrees in hot air oven. Paraffin wax tissue blocks were prepared for sectioning at 5 µ thicknesses using Reichert microtome. The obtained tissue sections were mounted on glass slides, deparaffinized, stained with Haematoxylin (Ehrlich) and counterstained by Eosin for routine examination then examination was done through the light electric microscope [22]. For histochemical study specimens were fixed in Carnoy’s fluid. Periodic acid Schiff’s reaction was used for demonstration of polysaccharides [23]. For immunohistochemistry examinations were used Caspase-3 (apoptotic marker), positive cells were determined with streptavidin-biotin-peroxidase staining method [24].

**Statistical analysis**

Results were expressed as mean±SD. All statistical analysis were done using Statistical Package for the Social Sciences (SPSS) (version 20), the T-test was performed to test the significance level between the treated groups and negative control group. Values of P<0.05 were considered statistically significant. The data analysis was performed using SPSS version 15.0.

**RESULTS**

**Placental toxicity**

The placenta is a temporary organ; it is an interface between the dam and developing embryos and a complex organ that have important roles that are modified throughout gestation period. The pregnant dams treated with 100 mg/Kg of topiramate drug showing a significant increase in the placental weight (0.74±0.03) compared to control group (0.52±0.02) as shown in (fig. A).

**Histopathological observations**

The microscopic examination of the placenta treated with TPM, an increase in a basal layer with a decrease of labyrinth zone of the placenta are recorded in comparison with control one (fig. 1). Histopathologically, placental necrosis and degeneration appear more commonly in the trophoblasts in the labyrinth zone (fig. 2). There is a reduction in thickness and disruption of the trophoblastic septa and irregular dilatation of maternal sinusoids with hemorrhagic sites (fig. 3). Enlarged maternal blood vessels with an increase in thickness of its endothelium are observed, this maternal blood vessel surround by bloody evidence (fig. 4). While the fetal blood vessels show degree of damage of endothelium (fig. 5).

**Fig. 1: Section of placenta stained with Haematoxylin and Eosin stain. Left fig. is the control pregnant rat showing normal basal zone (B), normal labyrinth zone (L), giant cell (Ga), spongiotrophoblast (ST). Right is the treated one demonstrating increasing in the basal zone (B) and decrease in the labyrinth zone (L), (Ga): giant cell, (ST): spongiotrophoblast**
In the basal zone, necrotic areas are detected. Also, the nuclei of spongiotrophoblast are characterised by karyorrhexis (fig. 6). An increase in numbers of glycogen cells are recorded, this glycogen cells undergo cytolysis and subsequently coalesce into multiple large cysts that are filled with a homogeneous acidophilic mass, and multiple clusters of residual glycogen granules, macrophages, erythrocytes and cell debris. Hyperemia (hemorrhagic cysts) was observed (fig. 7). The decrease in a number of major endocrine giant trophoblasts in comparison with control one (fig. 1). In addition, nuclei of it were characterised by pyknosis and odd shaped. Heterogenous cytoplasmic vacuoles of giant cells are evidence (fig. 8).

Fig. 3: Section of treated placenta stained with Haematoxylin and Eosin stain showing hemorrhagic areas (H) and dilation in the maternal sinusoid of labyrinth zone (L), (T): Trophoblast, (MS): maternal sinusoid

Fig. 4: Section of treated placenta stained with Haematoxylin and Eosin stain showing enlargement of the maternal blood vessels (MB) with increased the thickness of endothelium of the maternal blood vessels (EN), (H): hemorrhagic areas, (MS): maternal sinusoid, (T): trophoblast, (N): necrotic area

Fig. 5: Section of treated placenta stained with Haematoxylin and Eosin stain illustrating damage in the endothelium of fetal blood vessels (FB), (EN): maternal blood vessels, (L): labyrinth zone, (MS): maternal sinusoid

Fig. 6: Section of treated pregnant rat’s placenta stained with Haematoxylin and Eosin stain, showing some necrotic areas (N) in the basal zone, (ST): spongiotrophoblast

Fig. 7: Section of treated pregnant rat’s placenta stained with Haematoxylin and Eosin stain, showing cytolysis of glycogen cells (Gly C) and hemorrhagic cysts (stars), (N): necrotic areas

Fig. 8: Section of treated pregnant rat’s placenta stained with Haematoxylin and Eosin stain, showing alteration in nucleus (arrow) and cytoplasmic vacuoles of giant cells (Ga) (star)
Histochemical examination

The light microscopic investigation revealed that the placental tissue of the treated group showed positive Periodic acid Schiff's (PAS) reaction; specially coalesce glycogen cells (fig. 9) and spongio-trophoblasts of the basal zone (fig. 10), trophoblasts of labyrinth zone (fig. 11).

Immunohistochemical investigation

Also, different degree of the apoptotic index in trophoblasts is recorded using Caspase-3 as an indicator (fig. 12).

DISCUSSION

The relationships between the mother and fetus are very complex; these relations occur through the placental tissue and control development of the fetus. So, the placenta is the principle link between mother and its fetus, being responsible for the transfer of nutrients from maternal to fetal blood and for the clearance of waste metabolites from fetal blood across the labyrinth layers of the placental barrier. In addition, the placenta is a target organ for drug or chemical-induced adverse effects. Drug or chemical induced placentational functional depression and injury subsequently result in abnormal fetal growth or development leading to delay in growth of fetuses, fetal resorption and malformation. It is worthy to mention that; placenta is thus determinant for pregnancy success.

This is the first record showing that prenatal administration of topiramate causes a developmental alteration in the rat placental tissue. In Charles Foster rats fetuses, topiramate was administered orally at 40, 100 and 200 mg/kg doses from days 9 to 12 of gestation produced skeletal anomalies in a dose-related manner, but the fetal weight was not reduced [13, 25]. In contrary, maternal body weight was reduced significantly following administration of different doses of antiepileptic drugs in experimental animals [26, 27]. The increase in placenta weight with significance difference in this study may be to the maternal nutritional status. Although topiramate shows some promise as a therapeutic agent in epileptic pregnant women with lower risk of a teratogenic effect than other drugs [2] there are reports of its teratogenic effects in animals [15, 28]. Multiple sites of toxicity acting along the hypothalamic-pituitary-ovarian-uterine axis due to TPM administration explain the malformation in mother, fetuses and placenta. In second-generation antiepileptic drugs, during pregnancy hormonal changes, that is, increased estrogen levels, lead to accelerated drug glucuronidation in the liver. This condition appears to increase gradually throughout the first and second trimester, with little change during the last trimester [29]. Also, the activity of some CY P450 enzymes is increased [30].

Fig. 9: Section of pregnant rat's placenta stained with Periodic acid Schiff's. Left fig. is controlled; normal tissue structure, (Gly C): cytolysis of glycogen cells, (Ga): giant cell, (ST): spongio-trophoblast, (L): labyrinth zone. Right treated showing a positive reaction of Periodic Acid-Schiff's (PAS) in glycogen cells (Gly C), (Ga): giant cell, (ST): spongio-trophoblast, (L): labyrinth zone, (MS): maternal sinusoid

Left is normal control structure of trophoblasts (T) of labyrinth zone (L). Right treated showing a positive reaction of Periodic acid Schiff's (PAS) in trophoblasts (T) of labyrinth zone (L) (stars)
Multiple physiological pathways have been affected by topiramate. The main mechanism of teratogenic action which affects on different tissue in the body is oxidative stress [31, 32]. Topiramate was found to be a free radical scavenger [33] and its role as antioxidant indicates that its effect on placenta is not due to the presence of free radicals [16]. On the contrary, in this study, oxidative damage causes as an increase in caspase-3 activity as indicated in this manuscript, which would lead to increased apoptosis of cells [34], the oxidative damage is a result of the imbalance of free radicals production and antioxidant capacity. Mechanism of action of valproic acid is related to the changes in methylation of histones [35].

Epigenetic modification of them with hyperacetylation is accompanied with induction of apoptosis [36, 37]. The latter condition may be occurring in placental tissue causing a defect in its structure as well as its function.

TPM affects cell polarisation through effects on various ion channels [38]. It inhibits histone deacetylases; histone deacetylases are also inhibited by valproic acid [39]. In previous studies, treatment with topiramate was associated with metabolic acidosis due to its inhibitory action on carbonic anhydrase enzyme [40, 41], which leads to renal bicarbonate loss [42, 43]. These mechanisms may lead to alteration on the tissue of placenta in the present study.

CONCLUSION

Generally, the teratogenic mechanism of AEDs is only partially understood. So, it may be essential to study the effect of topiramate on similar signalling pathways that are altering different body tissue.
