INTRODUCTION

Natural products have been used over the years as curative agents against many infections and have been exploited in the traditional medicine with their curative potentials well documented [1-3]. Natural products are defined as natural sources-derived substances having biological activities. These natural products have long been implemented as alternative health care treatment and in the discovery of modern drugs [4]. A major focus of natural product in chemistry has been toward drug design and discovery. However, obtaining scientific proof for the biological activity of natural plants is still challenging [5, 6].

Leptadenia hastata despite the extensive uses, there have been only limited attempts to explore the biological activities of the plants in relation to their medicinal uses. It was reported that traditional healers use 2,500 plant species as regular sources of medicine [28]. Here, we present data on antimicrobial activities of the different extracts obtained from n-hexane, dichloromethane, ethyl acetate, chloroform and methanol of Leptadenia hastata plant species.

Leptadenia hastata (Pers.) Decne, which belongs to the family Asclepiadaceae, is a wild plant used as a vegetable by many African populations and as medicine due to its nutritive and therapeutic properties for the treatment of wounds and stomach upset conditions in children [7,8]. The plant Leptadenia hastata is an edible non-domesticated valuable herb with creeping latex stems, glabescent leaves, glomerulus and recemes flowers as well as follicle edible non-domesticated valuable herb with creeping latex stems, glabescent leaves, glomerulus and recemes flowers as well as follicle edible non-domesticated valuable herb.

Leptadenia hastata leaves: freshly leaves of Leptadenia hastata were collected from the uncultivated farmland of the Federal University Wukari Taraba State, Nigeria and was authenticated at Ahmadu Bello University Zaria and Voucher No PU: 2 ABU Herbarium No CM0003 were obtained from Oxoid Ltd, Wade Road, Basingstoke, Hants, RG2 8PW, UK. oxoid@oxoid.com.

Sample collection

Leptadenia hastata leaves: freshly leaves of Leptadenia hastata were collected from the uncultivated farmland of the Federal University Wukari Taraba State, Nigeria and was authenticated at Ahmadu Bello University Zaria and Voucher No PU: 2 ABU Herbarium No 900220. The plant Leptadenia hastata (yadiya) was dried under room temperature.

Preparation of samples

Fresh leaves of the plant Leptadenia hastata was washed with distilled water to remove the soil and dust particles, they are thoroughly air dried and powdered using laboratory grinder machine (FGR-350, Quest Scientific). Extraction using hexane by placing 150g of the powdered samples into an Erlenmeyers flask and hexane three times the weight of the extracts was added, the solution was covered and shaken at an interval of an hour and then allowed at room temperature to stand for 7 days. The mixture was then filtered using Whatman filter paper No.4 the residue was re-extracted with fresh hexane for another 72 h and filtered. Both extracts were combined and concentrated with a rotary evaporator (Heidolph Laborota 4000 efficient) under reduced pressure to

obtain the hexane crude extract. The residues were re-extracted using a similar procedure with dichloromethane (CH₂Cl₂), followed by ethyl acetate (C₂H₅COOH), chloroform (CHCl₃), and methanol (MeOH) to obtain dichloromethane, ethyl acetate, chloroform and methanol crude extracts, respectively. The dry weight and yield of each crude extracts were determined. It was then stored under a frozen condition until required.

**Antimicrobial assay**

Antimicrobial assays were conducted using the agar well disk diffusion method, Nutrient agar was used as media.

**Preparation of agar plates**

Preparation of agar plates was performed based on the method described by Ram Kumar and Pranay [25], with little modification. Nutrient agar was prepared according to manufacturer’s instruction with 14 g of dried agar dissolved in 500 ml distilled water. The agar solution was heated until boiling followed by sterilization in autoclave at 121 °C. The agar solution was then poured into a sterile petri plate and allowed to cool down and forming a gel. The plate was divided into eight sections by making a line marking on the outside surface of the plate. The eight sections were for each test samples namely 25 ppm, 50 ppm, 100 ppm, 250 ppm, 500 ppm and 1000 ppm samples, tetracycline 30 µg (positive control) and methanol (negative control). The plate was sealed using parafilm and kept chilled at 4 °C upon bacteria inoculation.

**Preparation of bacteria broth**

Several selected bacteria were used to evaluate the antibacterial activities of the crude extracts of *Leptadenia hastata*. *Escherichia coli*, *Salmonella typhi*, *Staphylococcus aureus* and *Klebsiella pneumonia* were obtained from the stock culture provided by Virology Laboratory, University Malaysia Sarawak. Nutrient agar was prepared according to manufacturer’s instruction, with 2.6 g of dried broth dissolved in 200 ml distilled water followed by sterilization in an autoclave at 121 °C. The bacteria were sub-cultured in a 10 ml of broth, each in a universal glass bottle for 16 h inside an incubator equipped with a shaker at 37 °C [26].

After 16 h incubation, turbidity (optical density/OD) of the bacterial broth was measured by using UV mini spectrophotometer (model 1240 of Shimadzu brand), comparable to that of nutrient broth standard tube for further use [27]. The measurement was performed at wavelength 575 nm and the bacterial broth was ready to be used when its turbidity is between OD 0.6 to 0.9. The nutrient broth was used to adjust the turbidity until the desired value was obtained.

**Plate inoculation**

Inoculation of the bacteria was carried out in a biohazard cabinet and the procedure was based on the method described by Ram Kumar and Pranay [26]. Approximately 1 ml of the ready bacterial broth were transferred into mini centrifuge tubes. A sterile cotton swap was dipped into the mini centrifuge tube containing bacteria broth and streaked over entire of the agar plate surface, performed in 4 different directions. The agar plate was then left for 5-10 min before applying the test samples. The disc used was 6 mm diameter. A volume of the directions. The agar plate was then left for 5-10 min before applying the test samples. The disc used was 6 mm diameter. A volume of the disc was measured by using parafilm and keep chilled at 4 °C upon bacteria inoculation.

**Antimicrobial activity**

The development of microbial resistance to presently available antibiotics has led to the search for new antimicrobial agents [16]. Due to the problem of microbial resistance to antibiotics, attention is given toward biologically active components isolated from plant species commonly used as herbal medicine, as they may offer a new source of antimicrobial activities [17]. Our search for antimicrobial bioactivity from tropical medicinal plant revealed the antimicrobial activity of five different solvent leaf extracts of *Leptadenia hastata*. Results of antimicrobial tests of the plant extracts are listed in table 1-4.

The extracts result as shown in table 1 do not show the much strong effect as when compared with the control, but it had some reasonable response in retarding the growth of the organism *salmonella typhi*.

In table 2 there is a progressive increase in the activities of the plant extracts on *Escherichia coli* with increase in the concentration of the solvent extract, this reflects a significant increase in the inhibition by 1.23±0.12 mm at 1000 ppm with (P<0.05) in the mean value of chloroform, methanol and 1.20±0.10 mm at 500 ppm ethyl acetate.

In table 3 extract from dichloromethane at 1000 ppm in the mean value of 1.33±0.06 mm showed higher activity against Staphylococcus aureus followed by methanol at 1.15±0.06 mm and chloroform 1.13±0.15 mm at the same concentration. The extracts present a significant antimicrobial activity but lower compared to the control. The association of antibiotics and plant extracts showed a substantial cooperation with the antibacterial activity against the bacteria. The results obtained with Staphylococcus aureus was particularly interesting since it was showing a gradual inhibition with increasing concentration with both polar and non-polar solvents extract. This inhibition was observed with the individual extracts and when it is used at higher concentrations.

In table 4 the results of effects of the leaf extract from various concentrations of hexane, ethyl acetate, dichloromethane, chloroform and methanol of *Leptadenia hastata* on the radial growth of *Klebsiella pneumonia* reveals growth is more inhibited at extract for hexane, dichloromethane, and ethyl acetate, they showed high activities against klebsiella pneumonia with the zone of inhibition of 0.50±0.00 mm-1.23±0.06 mm from 25 ppm, 50 ppm, 100 ppm 250 ppm 500 ppm and 1000 ppm compared to chloroform and methanol extract with an inhibition rate of 0.62±0.01 mm-1.70±0.26 mm. Very low compared to the control (2.00±0.01). The chloroform and methanol crude extract showed weak activities against Klebsiella pneumonia. However, the rate of inhibition increases with the increase in concentrations.

Alero and Wara [23] that Methanol and water extract s from the hypertension and tumors [19-22]. In agreement with the report of important role in growth inhibition against bacteri a, fungi, viruses, 

Leptadenia hastata ethyl acetate and chloroform were all active in asc ending order 

However, the activity observed from the hexane, dichloromethane, ethyl acetate and chloroform were all active in ascending order. The growth of enterohemorrhagic strain of Escherichia coli, however, is suggesting the possibility for the treatment of diseases caused by this microorganism; Staphylococcus aureus, Escherichia coli and Salmonella Para typhi.

DISCUSSION

The antibacterial activity results of Leptadenia hastata extracts are summarized by the paper disc diffusion methods as shown in the tables above. The results of the disc diffusion method in terms of the size zone of inhibition (mm) for the extracts were compared against the bacteria’s studied.

The highest inhibitory activity was determined, methanolic extract showed the highest effect with a clearing zone of 1.10±0.10 mm and 0.97±0.06 mm a against salmonella typhi; relative to the control tetracycline (table 1). Salmonella enterica typhi, is an obligate parasite which leads to the development of typhoid fever [18]. In previous studies, Leptadenia hastata has been reported to play an important role in growth inhibition against bacteria, fungi, viruses, hypertension and tumors [19-22]. In agreement with the report of Alero and Wara [23] that Methanol and water extracts from the leaves of Leptadenia hastata showed antibacterial activities. However, the activity observed from the hexane, dichloromethane, ethyl acetate and chloroform were all active in ascending order when compared with the drug control. The action of Leptadenia hastata on Escherichia coli, and Staphylococcus aureus is instructive. Although Escherichia coli belongs to the normal flora of humans, an enterohemorrhagic strain of Escherichia coli has caused serious food poisoning and preservatives, thus to eliminate its growth are needed [24]. The susceptibility of Staphylococcus aureus to the extract of this plant may be an indicator to its potential as a drug that can be used against this organism.

The growth of Staphylococcus aureus, Escherichia coli and 

CONCLUSION

The present work has proved that the extracts of leaves from (n-hexane, dichloromethane, ethyl acetate, chloroform and methanol) possessed antimicrobial properties. The present results showed the potential of the medicinal plant used by traditional herbal medical practitioners as natural antimicrobial agents, thus can be further used to determine the bioactive natural products that may provide as leads in the development of new drugs. This study reconfirmed the potential of the medicinal plant used by traditional herbal medical practitioners as natural antimicrobial agents, thus can be further used to determine the chemical identity of the bio-active compounds responsible for the observed antimicrobial activity. However, efforts are ongoing to characterize and explore the phytochemical properties of the contributory compounds present in the extract in University Malaysia (unimas).
